

# Oracle at CERN Database technologies

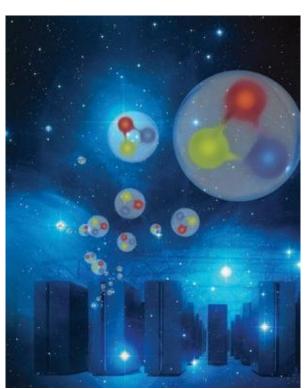

Image courtesy of Forschungszentrum Jülich / Seitenplan, with material from NASA, ESA and AURA/Caltech

Eric Grancher, eric.grancher@cern.ch Maaike Limper, maaike.limper@cern.ch CERN IT department

### **Outline**

- Experience at CERN
  - Current usage and deployment
  - Replication
  - Lessons from last 15 years
- Oracle and MySQL
- Trends
  - Flash
  - Compression
  - Open source "relational" databases
  - NoSQL databases

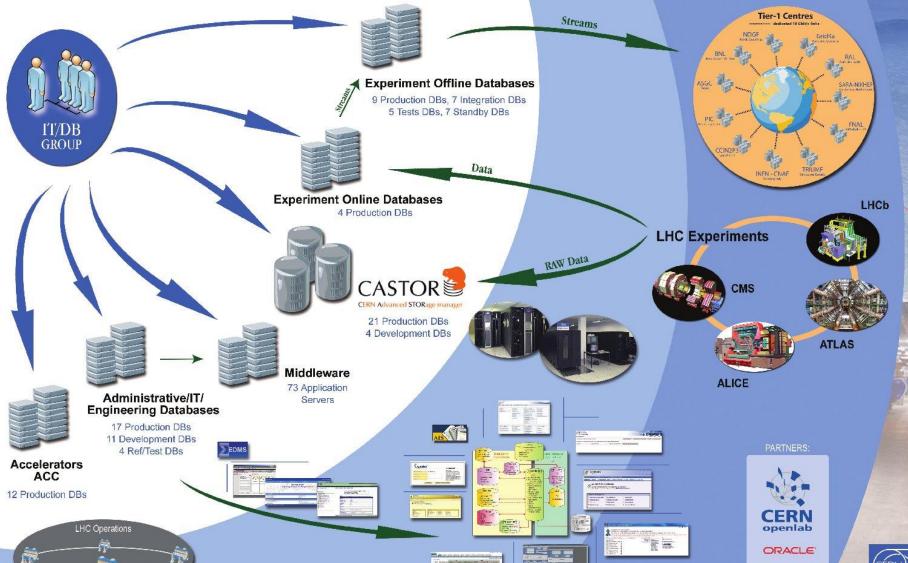

http://cern.ch/it-dep/db/

#### At the heart of CERN, LHC and Experiment Operations

CERN T Department

### CERN databases in numbers

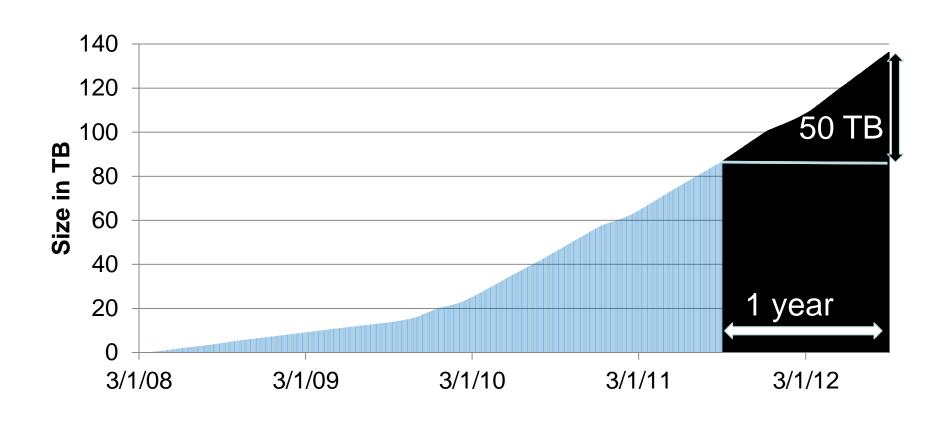

#### CERN databases services

- ~130 databases, most of them database clusters (Oracle RAC technology RAC, 2 – 6 nodes)
- Currently over 3000 disk spindles providing more than ~3PB raw disk space (NAS and SAN)
- MySQL service
- Some notable databases at CERN
  - Experiments' databases 14 production databases
    - Currently between 1 and 12 TB in size
    - Expected growth between 1 and 10 TB / year
  - LHC accelerator logging database (ACCLOG) ~120TB,
     >5\*10<sup>12</sup> rows, expected growth up to 70TB / year
  - Several more DBs in the 1-10 TB range

### LHC logging service, > 5 \* 10<sup>12 rows</sup>

### Key role for LHC physics data processing

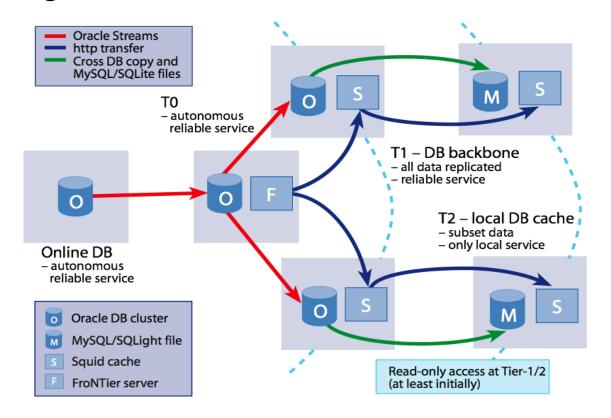

- Online acquisition, offline production, data (re)processing, data distribution, analysis
  - SCADA, conditions, geometry, alignment, calibration, file bookkeeping, file transfers, etc..
- Grid Infrastructure and Operation services
  - Monitoring, Dashboards, User-role management, ...
- Data Management Services
  - File catalogues, file transfers and storage management, ...
- Metadata and transaction processing for custom tape-based storage system of physics data
- Accelerator control and logging systems
- AMS as well: data/mc production bookkeeping and slow control data

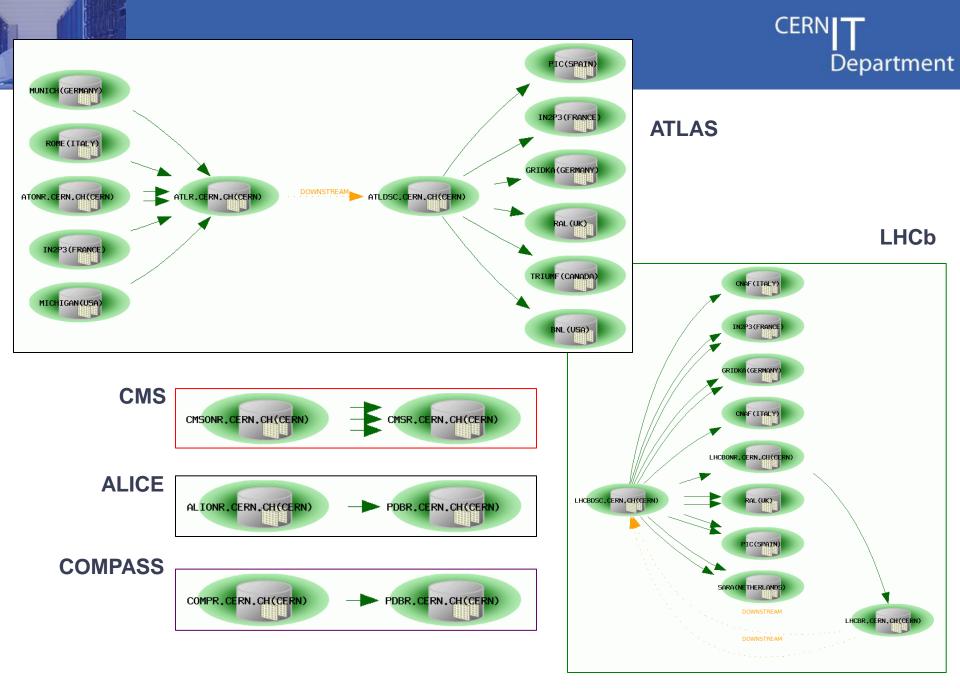

### CERN openlab and Oracle Streams

 Worldwide distribution of experimental physics data using Oracle Streams

Huge effort, successful outcome

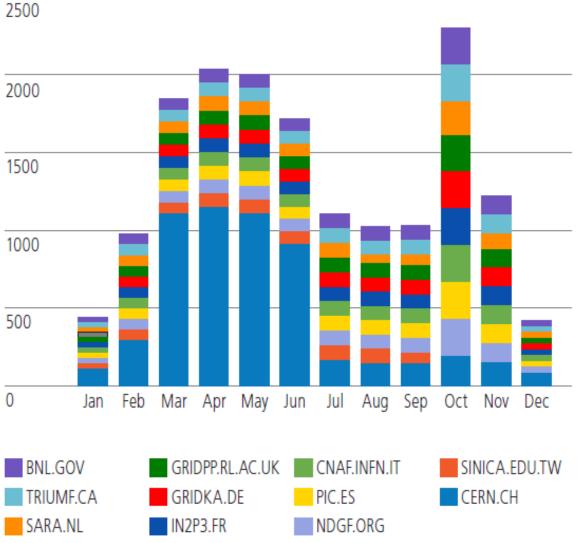

slide by Eva Dafonte Pérez 8

# Number of Logical Change Records (LCRs) in Millions, per Month, by Tier-1 Site

Replication rate for conditions data from the ATLAS experiment to the different WLCG Tier-1 sites in 2010

## Oracle is fully instrumented

- All actions
  - Network related
  - IO related
  - Internals (cluster communication, space management, etc.)
  - Application related (transaction locks, etc.)
  - etc.
- Key for "scientific" performance understanding.

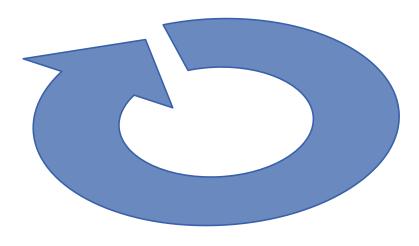

### The Tuning Process

1. run the workload, gather ASH/AWR information, 10046...

4. modify client code, database schema, database code, hardware configuration

2. find the top event that slows down the processing

3. understand why time is spent on this event

### Demo 1

- Single.java
  - Tanel Poder's snapper.sql
  - Disable autocommit
  - Tanel Poder's snapper.sql
- Batch.java

	Program	Time per row	Top wait event	Notable statistics
* 2.45	Single	0.76 ms / row	log file sync 57.1%	User commits=user calls=1.4k/s
2.40	Single autocommit=false	0.31 ms/row	SQL*Net message from client 69.9%	Requests to/from client = execute count= 3.69k/s
* 267	Batch	0.00116 ms	log file sync 18.4%, SQL*Net message from client 19.0%	

### Oracle Real Application Cluster

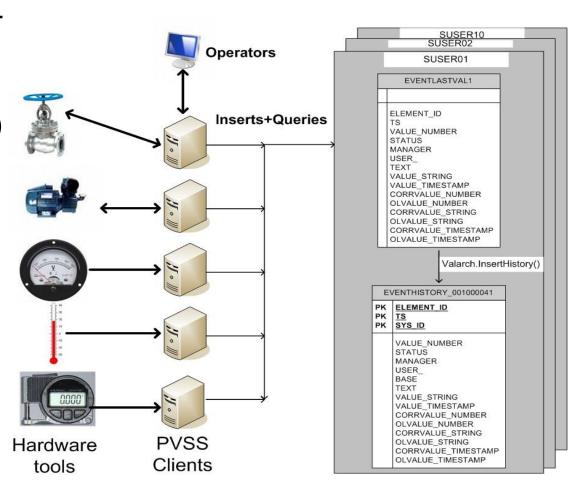

### **PVSS Oracle scalability**

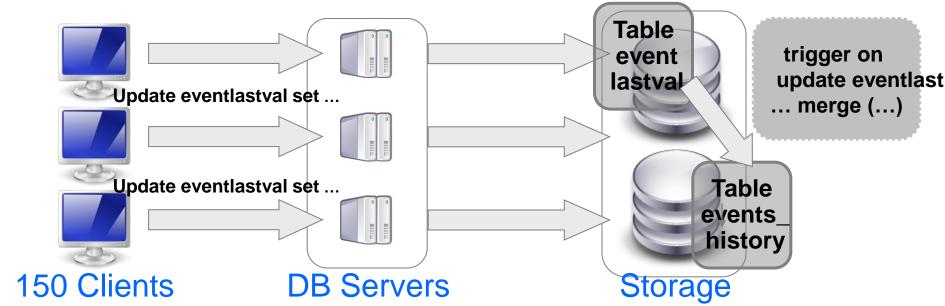

- Target = 150 000 changes per second (tested with 160k)
- 3 000 changes per client
- 5 nodes RAC 10.2.0.4
- 2 NAS 3040, each with one aggregate of 13 disks (10k rpm FC)

### PVSS Tuning (1/6)

Shared resource:

EVENTS\_HISTORY (ELEMENT\_ID, VALUE...)

 Each client "measures" input and registers history with a "merge" operation in the EVENTS\_HISTORY table

#### Performance:

100 "changes" per second

### PVSS Tuning (2/6)

#### Initial state observation:

- database is waiting on the clients
   "SQL\*Net message from client"
- Use of a generic library C++/DB
- Individual insert (one statement per entry)
- Update of a table which keeps "latest state" through a trigger

### PVSS Tuning (3/6)

#### Changes:

 bulk insert to a temporary table with OCCI, then call PL/SQL to load data into history table

#### Performance:

2000 changes per second

Now top event: "db file sequential read"

	i		<u>awrrpt 1</u>	5489 5490.html
Event	Waits	Time(s)	Percent Total DB Time	<b>Wait Class</b>
db file sequential read	29,242	137	42.56	User I/O
enq: TX - contention	41	120	37.22	Other
CPU time		61	18.88	
log file parallel write	1,133	19	5.81	System I/O
db file parallel write	3,951	12	3.73	System I/O

### PVSS Tuning (4/6)

#### Changes:

- Index usage analysis and reduction
- Table structure changes. IOT.
- Replacement of merge by insert.
- Use of "direct path load" with ETL

#### Performance:

- 16 000 "changes" per second
- Now top event: cluster related wait event

test5 rac node1 8709 8710.html

Event	Waits	Time(s)	Avg Wait(ms)	% Total Call Time	Wait Class
gc buffer busy	27,883	728	26	31.6	Cluster
CPU time		369		16.0	
gc current block busy	6,818	255	37	11.1	Cluster
gc current grant busy	24,370	228	9	9.9	Cluster
gc current block 2- way	118,454	198	2	8.6	Cluster

### PVSS Tuning (5/6)

#### Changes:

- Each "client" receives a unique number.
- Partitioned table.
- Use of "direct path load" to the partition with ETL

#### Performance:

- 150 000 changes per second
- Now top event : "freezes" once upon a while

#### rate75000\_awrrpt\_2\_872\_873.html

Event	Waits	Time(s)	Avg Wait(ms)	% Total Call Time	Wait Class
row cache lock	813	665	818	27.6	Concurrency
gc current multi block request	7,218	155	22	6.4	Cluster
CPU time		123		5.1	
log file parallel write	1,542	109	71	4.5	System I/O
undo segment extension	785,439	88	0	3.6	Configuration

### PVSS Tuning (6/6)

#### Problem investigation:

- Link between foreground process and ASM processes
- Difficult to interpret ASH report, 10046 trace

#### Problem identification:

ASM space allocation is blocking some operations

#### Changes:

Space pre-allocation, background task.

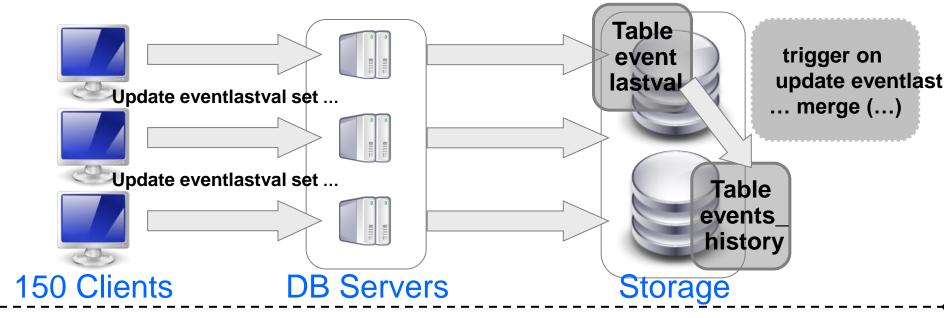

#### Result:

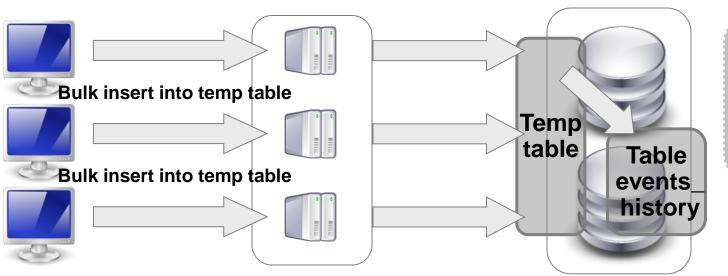

Stable 150 000 "changes" per second.

### **PVSS Tuning Schema**

PL/SQL: insert /\*+ APPEN into eventh (... partition PARTITION (1) select ... from temp

### **PVSS Tuning Summary**

#### Conclusion:

- from 100 changes per second to 150 000 "changes" per second
- 6 nodes RAC (dual CPU, 4GB RAM), 32 disks SATA with FCP link to host
- 4 months effort:
  - Re-writing of part of the application with changes interface (C++ code)
  - Changes of the database code (PL/SQL)
  - Schema change
  - Numerous work sessions, joint work with other CERN IT groups

### Overload at CPU level (1/)

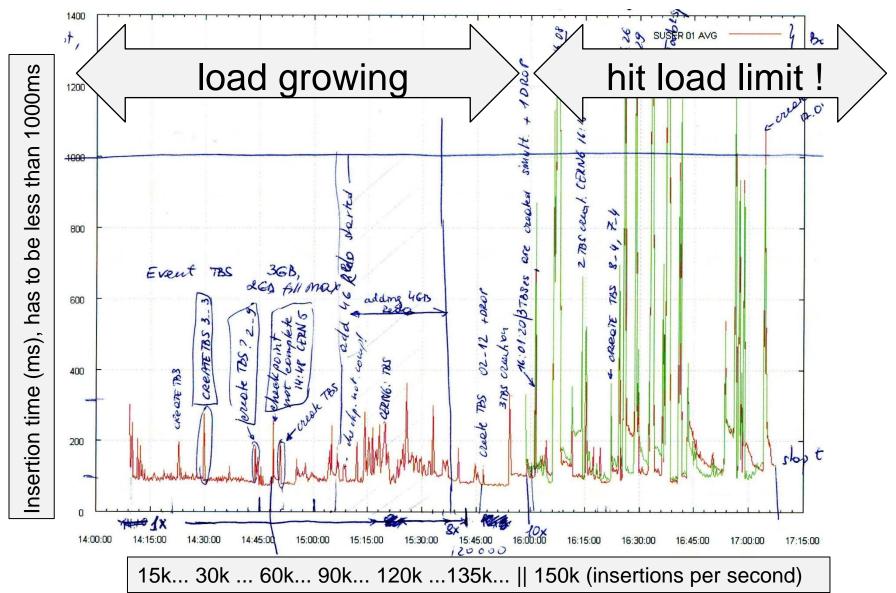

- Observed many times: "the storage is slow" (and storage administrators/specialists say "storage is fine / not loaded")
- Typically happens that observed (from Oracle rdbms point of view) IO wait times are long if CPU load is high
- Instrumentation / on-off cpu

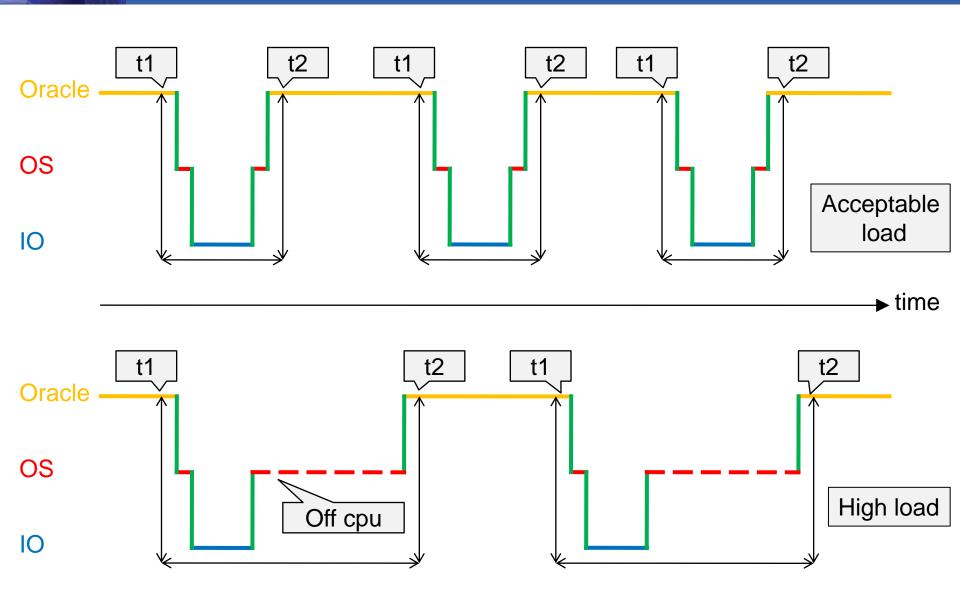

### Overload at CPU level (2/) example

## OS level / high-load

# Overload at CPU level (3/), Dtrace

 Dtrace (Solaris) can be used at OS level to get (detailed) information at OS level

```
syscall::pread:entry
/pid == $target && self->traceme == 0 /
 self->traceme = 1;
  self->on = timestamp;
  self->off= timestamp;
  self->io start=timestamp;
syscall::pread:entry
/self->traceme == 1 /
 self->io start=timestamp;
syscall::pread:return
/self->traceme == 1 /
  @avgs["avg io"] = avg(timestamp-self->io start);
  @[tid,"time io"] = quantize(timestamp-self->io start);
 @counts["count io"] = count();
```

#### **Dtrace**

```
sched:::on-cpu
/pid == $target && self->traceme == 1 /
  self->on = timestamp;
 @[tid, "off-cpu"] = quantize(self->on - self->off);
  @totals["total cpu off"] = sum(self->on - self->off);
  @avgs["avg cpu off"] = avg (self->on - self->off);
  @counts["count cpu on"] = count();
sched:::off-cpu
/self->traceme == 1/
  self->off= timestamp;
 @totals["total cpu on"] = sum(self->off - self->on);
  @avgs["avg cpu on"] = avg(self->off - self->on);
  @[tid, "on-cpu"] = quantize(self->off - self->on);
 @counts["count cpu off"] = count();
tick-1sec
/i++>=5/
 exit(0);
```

### Dtrace, "normal load"

```
-bash-3.00$ sudo ./cpu.d4 -p 15854
dtrace: script './cpu.d4' matched 7 probes

```

#### Lessons learnt

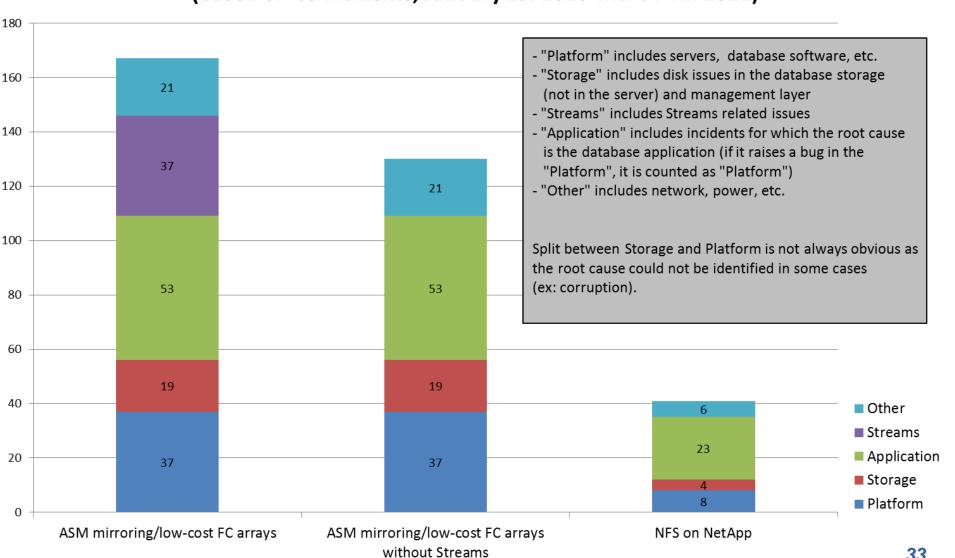

- Aiming for high-availability is (often) adding complexity... and complexity is the enemy of availability
- Scalability can be achieved with Oracle Real Application Cluster (150k entries/s for PVSS)
- Database / application instrumentation is key for understanding/improving performance
- NFS/D-NFS/pNFS are solutions to be considered for stability and scalability (very positive experience with NetApp, snapshots, scrubbing, etc.)
- Database independence is very complex if performance is required
- Hiding IO errors from the database leaves the database handle what it is best at (transactions, query optimisation, coherency, etc.)

#### Incidents review

#### **Breakdown of incidents** (based on C5 incidents, January 1st 2010-March 4th 2011)

- Flash
- Large memory systems, in memory databases
- Compression
- Open source "relational" databases
- NoSQL databases

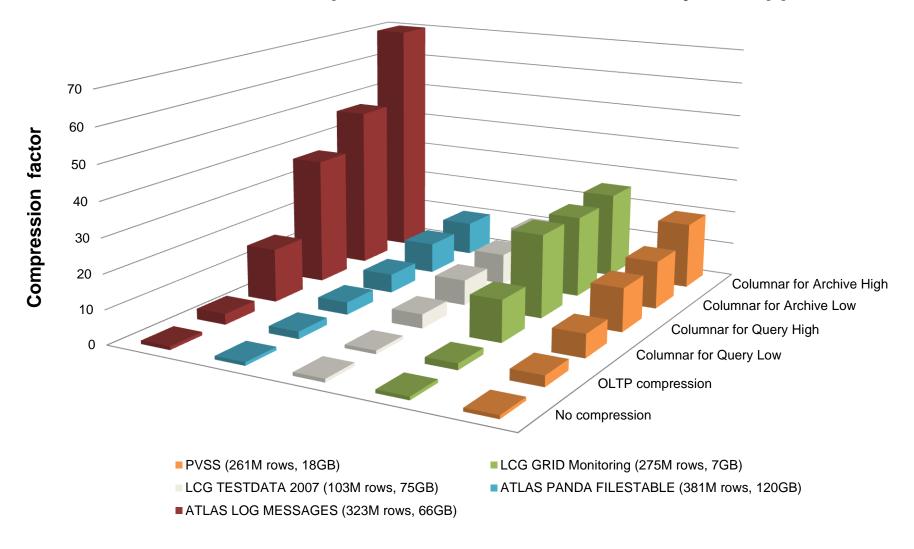

## Flash, memory and compression

- Flash changes the picture in the database area IO
  - Sizing for IO Operations Per Second
  - Usage of fast disks for high number of IOPS and latency
- Large amount of memory
  - Enables consolidation and virtualisation (less nodes)
  - Some databases fully in memory
- Compression is gaining momentum for databases
  - For example Oracle's hybrid columnar compression
  - Tiering of storage

#### Exadata Hybrid Columnar Compression on Oracle 11gR2

#### **Measured Compression factor for selected Physics Apps.**

### Local analysis of data

- "Big Data", analysis of large amount of data in reasonable of time
- Goole MapReduce, Apache Hadoop implementation
- Oracle Exadata
  - Storage cells perform some of the operations locally (Smart Scans, storage index, column filtering, etc.)
- Greenplum
  - shared-nothing massively parallel processing architecture for Business Intelligence and analytical processing
- Important direction for at least the first level of selection

### Open source relational databases

N**T** Department

- MySQL and PostgreSQL
- Some components are not "free", replacements exist (for example for hot backup Percona XtraBackup)
- MySQL default for many applications (Drupal, etc.)
- PostgreSQL has a strong backend with Oracle-like features (stored procedures, write-ahead logging, "standby", etc.)

- Oracle
  - Critical component for LHC accelerator and physics data processing
  - Scalable and stable, including data replication
- CERN central services run on Oracle, for which we have components and experience to build high availability, guaranteed data, scalability
- MySQL as a "DataBase On Demand" service
  - Nice features and light, lacks some scalability and High-Availability features for some service requirements
- NoSQL/scale-out SQL is being considered
  - Ecosystem is evolving rapidly (architecture, designs and interfaces subject to change!)

### Incidents review

### Breakdown of incidents per server (based on C5 incidents, January 1st 2010-March 4th 2011)

### Oracle

- EU director for research, Monica Marinucci
- Strong collaboration with CERN and universities
- Well known solution, easy to find database administrators and developers, training available
- Support and licensing
