

# RHIC Experimental Background

Angelika Drees and Wolfram Fischer

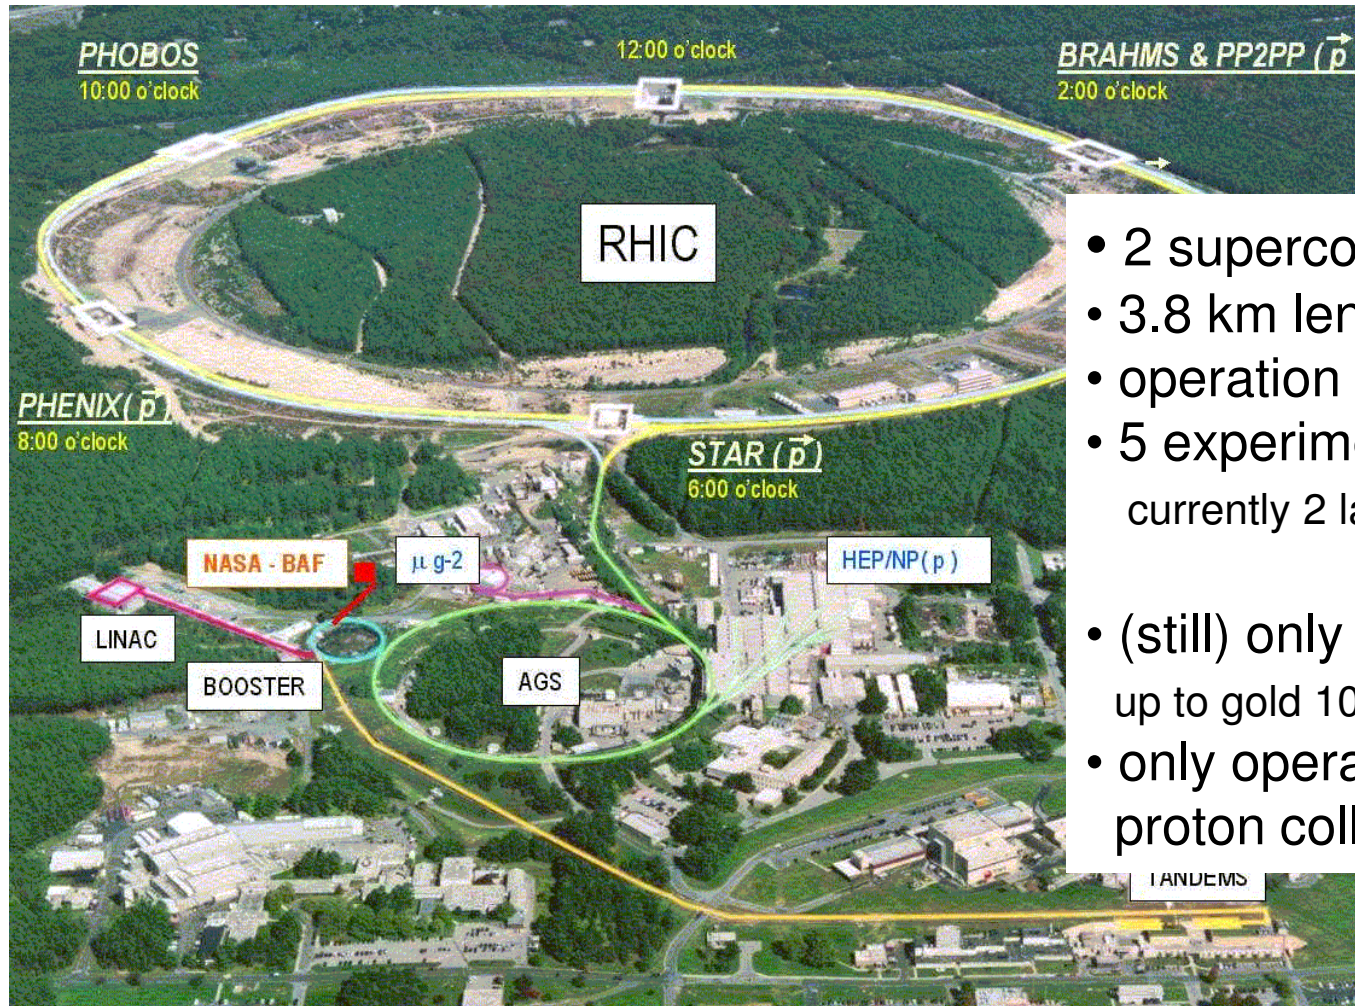

Workshop on Experimental Conditions and  
Beam Induced Detector Backgrounds, CERN

3 April 2008

# Topics

- RHIC overview
- Collimator layout and control
- Experimental background signals and control
- Beam-gas background

# Relativistic Heavy Ion Collider

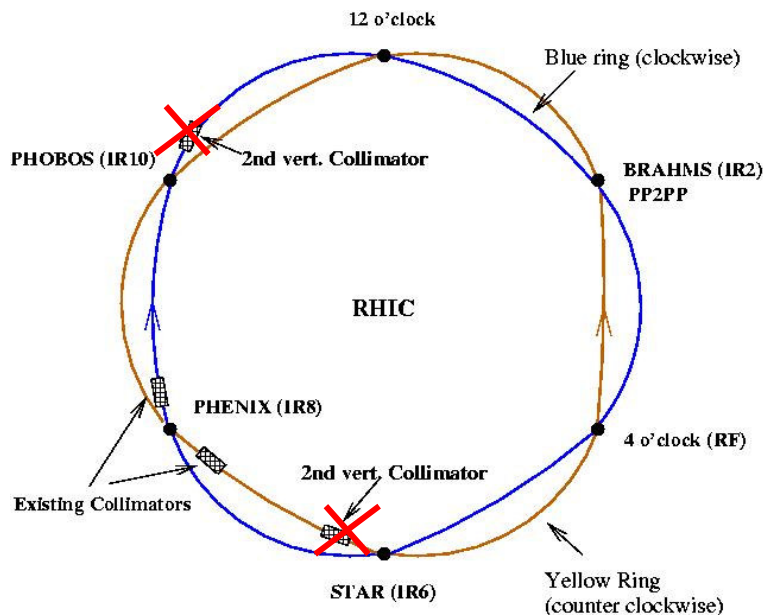

- 2 superconducting rings
- 3.8 km length
- operation since 2000
- 5 experiments so far, currently 2 large ones
- (still) only operating ion collider up to gold 100 GeV/nucleon
- only operating polarized proton collider

# RHIC running modes to date

- Au–Au                    4.6, 10, 28, 31, 65, 100 GeV/n
- d–Au                    100 GeV/n
- Cu–Cu                    11, 31, 100 GeV/n
- polarized p–p        11, 31, 100, 205, 250 GeV

**Some modes only for days – fast machine setup essential.**

# Collimator Layout

- Collimators around IR8
- Primaries are dual plane (L-shaped)
- All collimators have single jaw
- All collimators are in one straight section between Q3 and Q4
- Each collimator has a set of local loss monitors (Pin diodes)
- 2<sup>nd</sup> vertical collimators are not used (not efficient)

In RHIC collimators are used for experimental background reduction and abort gap cleaning only!

# A RHIC collimator

# Collimator Control: setup

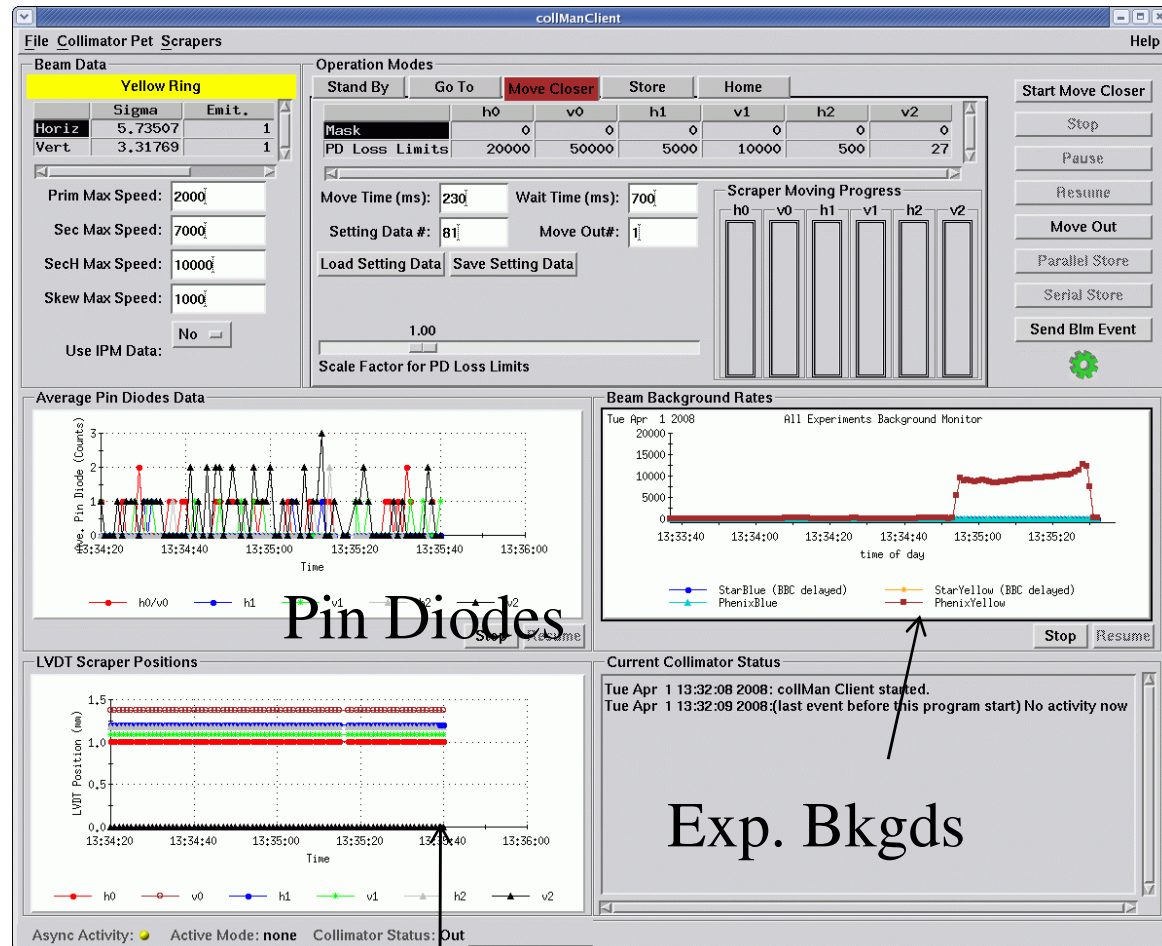

## Move Closer

Used for setting up collimators:

Uses local loss monitor (Pin Diodes) signal to stop movement

Moves all collimator jaws (5) in preset order (typically plane by plane)

Fine adjustment is done with "Store" mode afterwards

Pin Diodes

Exp. Bkgds

Collimator position

# Collimator Control: adjust

Final adjustments can be done in units of:

- Sigma
- mm
- Steps

Fine adjustments typically need to be done every other store. Final set points will be saved in to preset position. Quality is based on exp. Bkgd. Signal and strongly depends on their quality.

# Collimator Control: operation

Automatic ramp/store sequencer moves collimators into preset “goTo” position. These positions typically drift slightly from store to store and are optimized manually at the beginning of each store.

# Experimental Background signals

- Collimation efficiency strongly depends on reliability, availability and quality of experimental background signals.
- Typical problems:
  - Signal depends on detectors that are not turned on early in the store
  - Signals depends on DAQ to run (unreliable)
  - Signals are not compatible between experiments
  - Upper limits apply and keep changing between years and depend on shielding
  - Signals are contaminated with collision contributions
    - Amounts of that contamination varies between years and experiments
- Provided background signals are substantially different between the experiments!
  - PHENIX: tunnel scintillators
  - STAR: out of time signal from their BBC detector (directional)

# Communication with experiments

Experiments can view the RHIC elog.

Communication via TV screens and telephone

Information Exchange GUI: BERT with input from the experiments

The screenshot shows a window titled "BERT: Experiment-MCR Information Exchange" with a "Setup Diagnostics" tab. The window displays the following information:

**Machine State**

- Physics: **OFF** (indicated by a green dot)
- Beam Status: **No Beam**
- Steering Status: **Not Steering**

**Ring State**

- BLUE: **Scheduled Shutdown**
- YELLOW: **Scheduled Shutdown**

**Bunches**: 109 (for both BLUE and YELLOW)

**Collimator Status**: Out (for both BLUE and YELLOW)

**Experiment State**

|           | Vote/Status | # Coll. Bunches | Background Levels |
|-----------|-------------|-----------------|-------------------|
| BRAHMS    | Don't Care  | 37              | Undeclared        |
| PHENIX    | Undeclared  | 56              | Undeclared        |
| STAR      | Undeclared  | 52              | Undeclared        |
| POLAR JET | Don't Care  | 52              | Undeclared        |

Apr 1, 2008 3:04:35 PM: Ion Species in YELLOW: Au

# Collimation per plane:

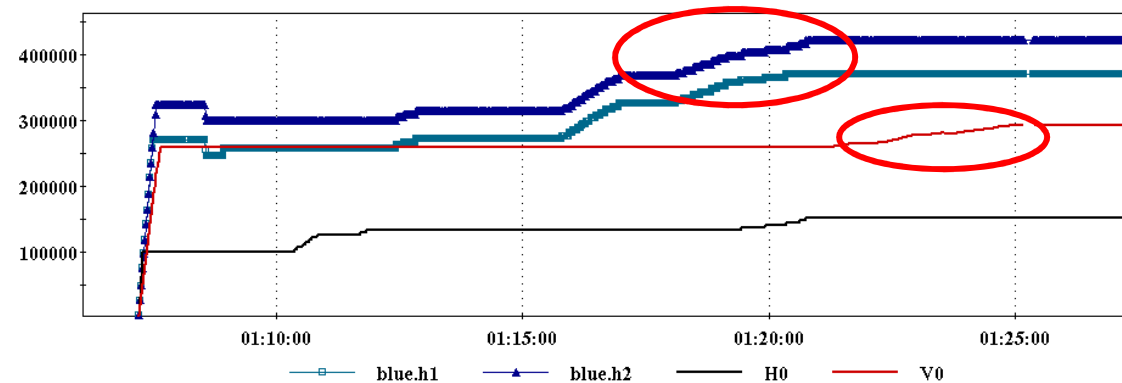

Individual planes on the following slide

Q2: max. of beta fct. In horizontal plane

Q3: max of beta fct. In vertical plane

The two planes are fully decoupled!

The STAR signal is inclusive and sees an effect for both planes.

## Horizontal Plane

Rate (Hz)

## Vertical Plane

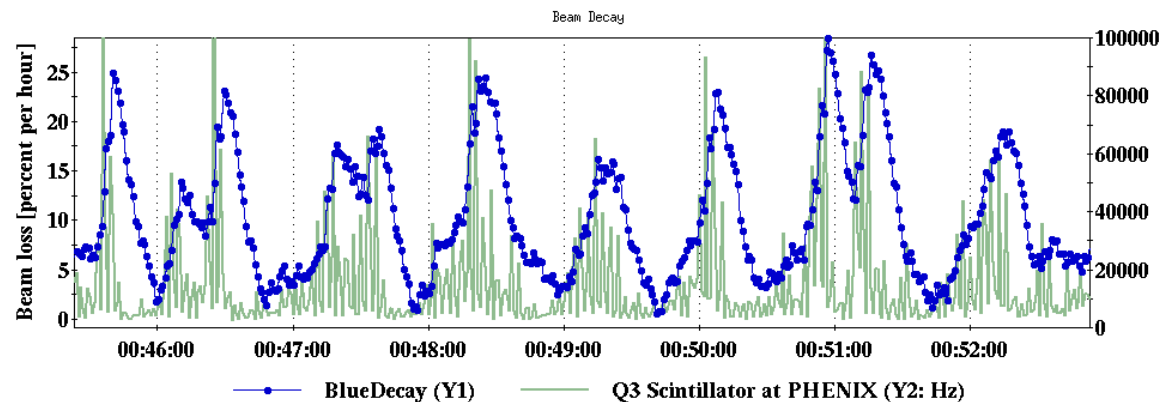

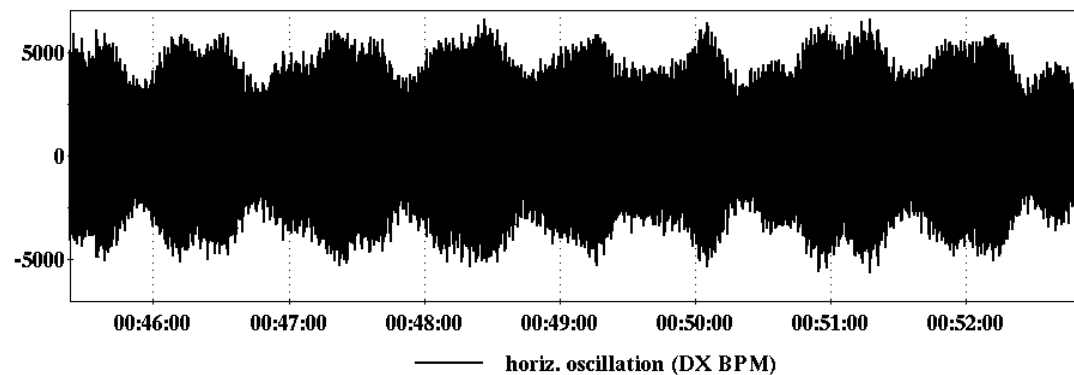

Achieved reduction rate during this collimation setup was in PHENIX x30 (h) and x15 (v) and x30 in STAR.

# Collimation depends on working point: near integer

In 2008 a near integer working point was tested in the Blue ring, the beam was very sensitive to orbit errors

10 Hz oscillations caused by mechanical triplet vibrations

Near integer caused the beam decay and background amplitudes to oscillate by an order of magnitude (beating of multiple sources)

# IR Steering

Angle steering (here Blue horizontal angle in IR8) helps experimental backgrounds.

Should be done before collimation since collimators are around IR8 and local beam position changes with IR steering

Reduction here  $\approx 30\%$

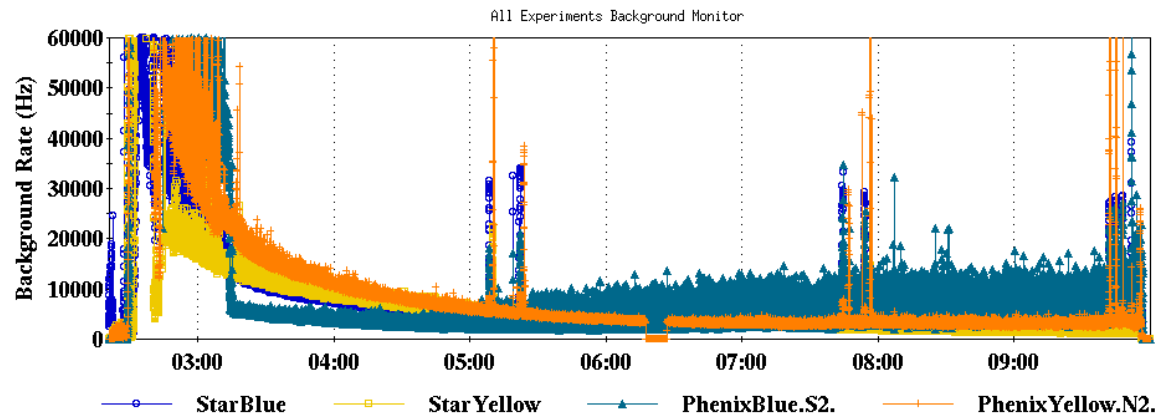

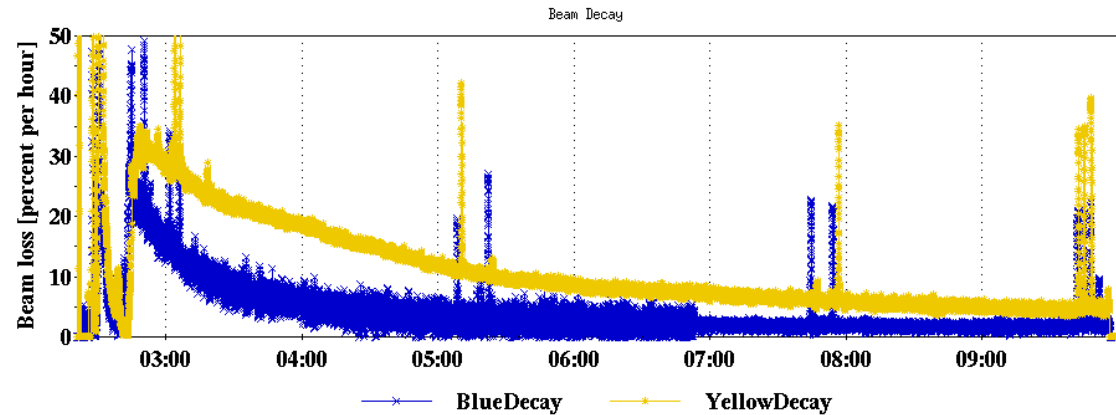

# Increasing backgrounds

Beam decay is stable while blue backgrounds increase during the store (happens in only a few stores).

Small drifts and beam growth cause additional scraping in the triplet while beam loss is not visibly increased.

Main cause: 24h period vertical orbit variations (have orbit correction every  $\frac{1}{2}$  h now)

# Collision contamination of signal

## PHENIX

Data taken during a vernier scan with the yellow beam.

South: blue backgrounds  
North: yellow backgrounds

N4-N6 and S4-S6 are collision dominated.  
North triplet scintillators see background caused by scan and the collimators being out.

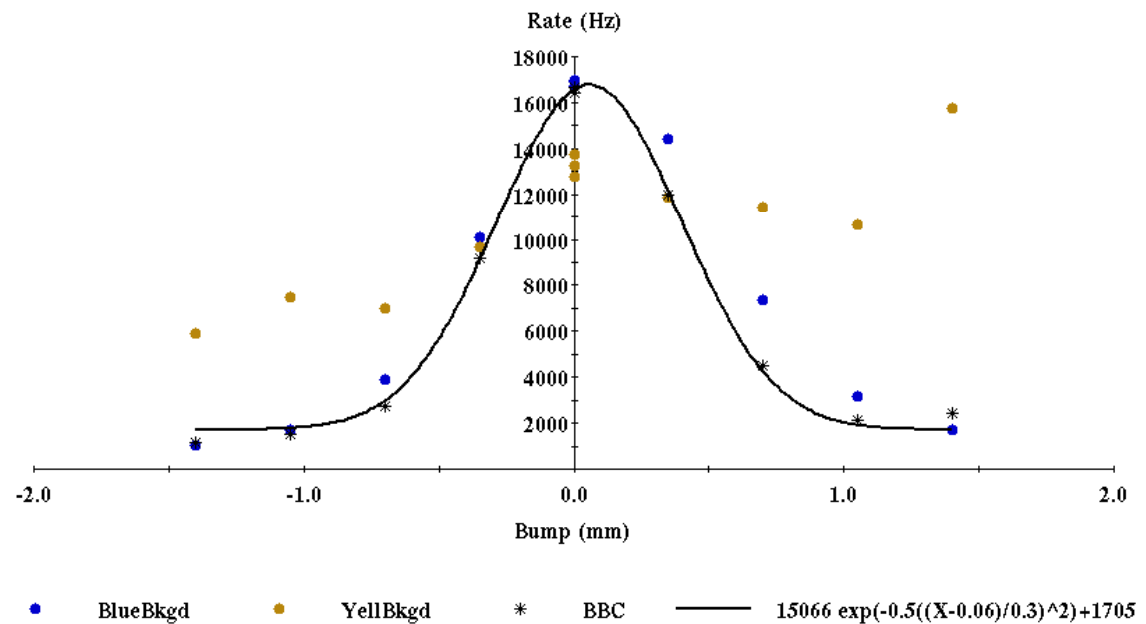

# Collision Contamination of signal

STAR

Data taken during a vernier scan (using the yellow beam).

Blue background signal is dominated by collision component.

Yellow background signal is partially collision signal, moving to +0.5 mm cause yellow background.

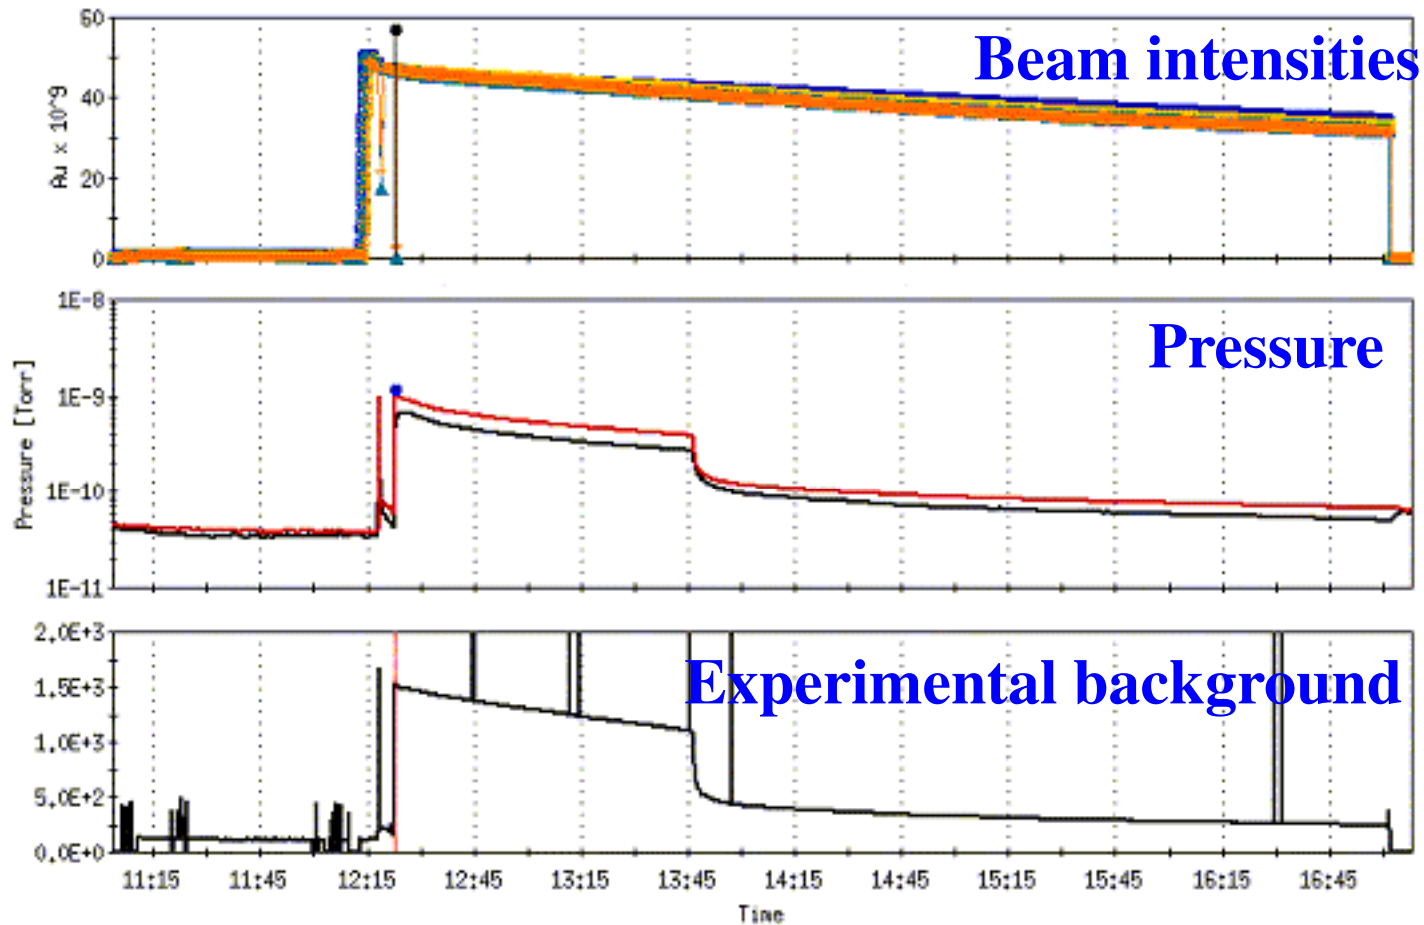

# Beam-gas backgrounds

Two experiments of concern:

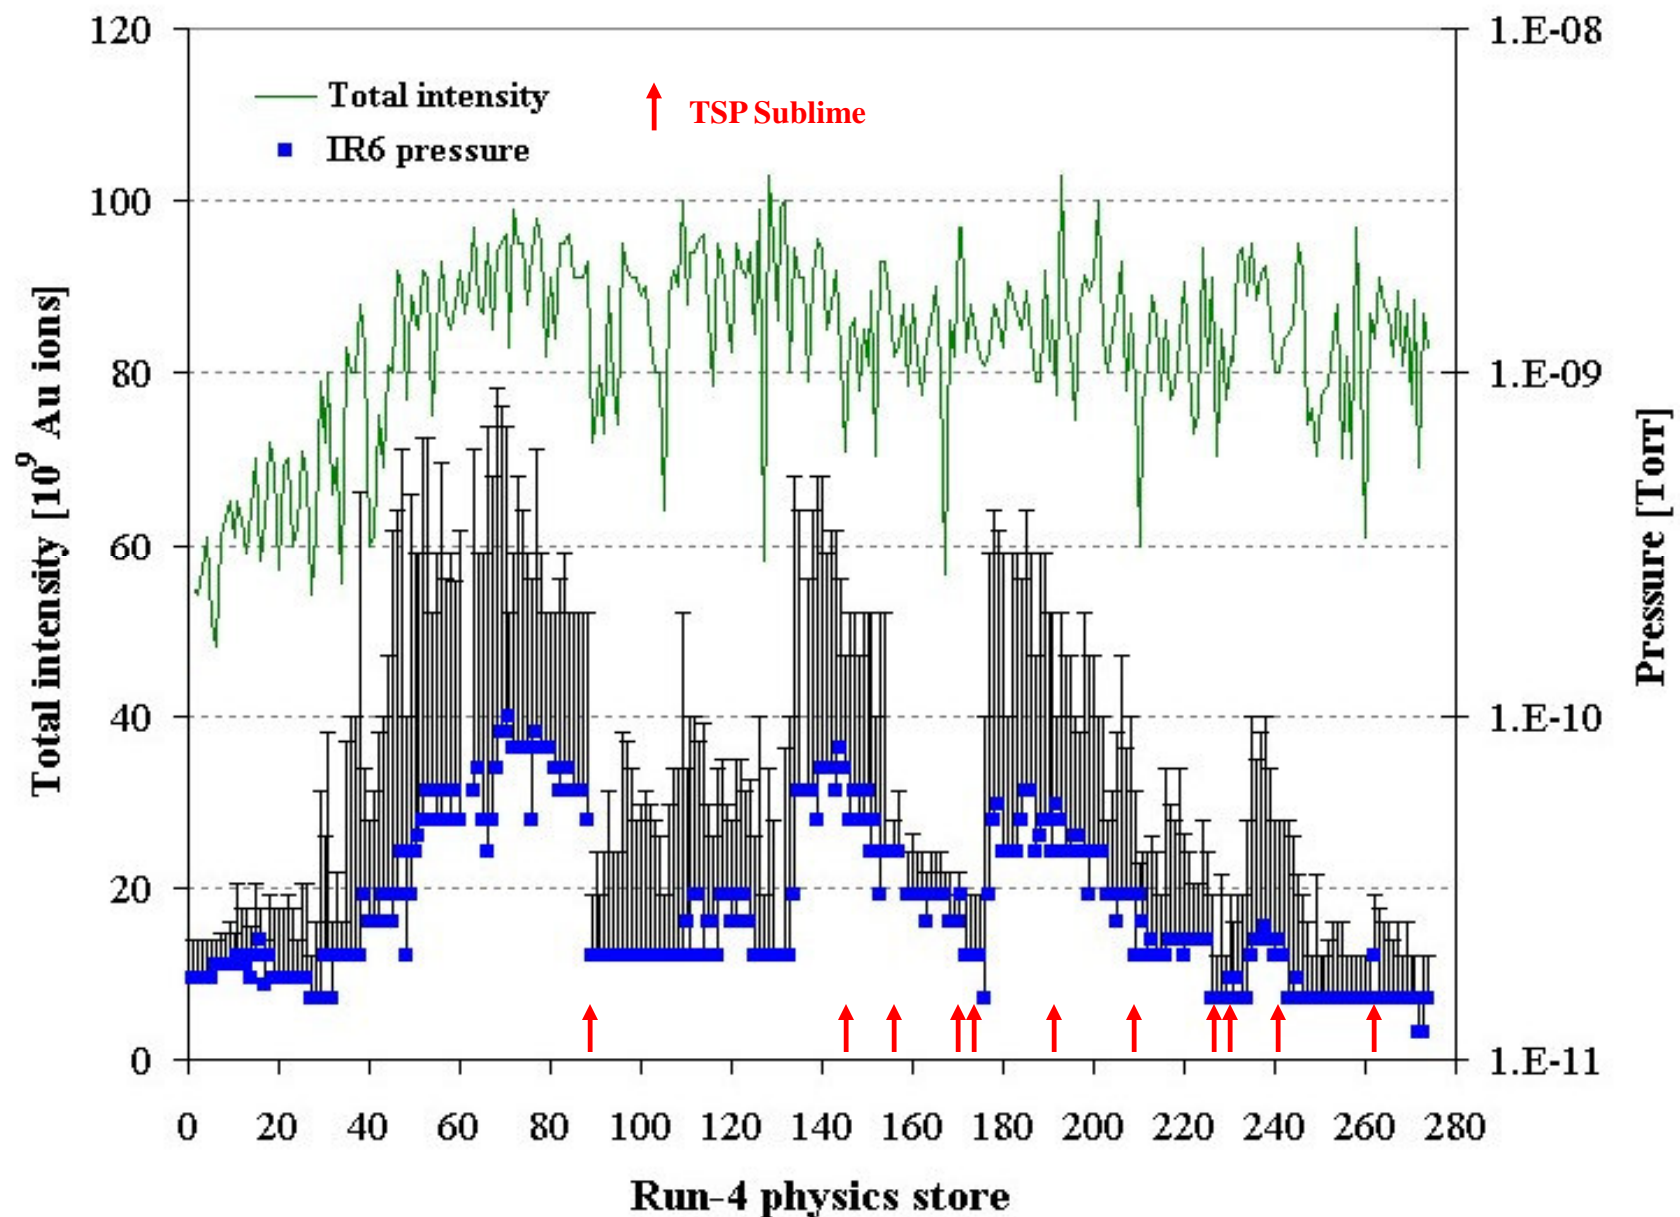

- **PHOBOS:**  
e-cloud induced dynamic pressure  
→ limited luminosity for all experiments – experiment now finished  
(12m beryllium pipe – not NEG coated)
- **STAR:**  
- background without periodic TSP reconditioning,  
or after polarity change (→ conditions after a few days)  
(for heavy ions only – beam pipe only hot flushed with N<sub>2</sub> at 70°)

**PHOBOS:** pressure rise after rebucketing (bunch length shortened), sudden pressure drop ~1h later (12m Be)

G. Rumolo, W. Fischer, BNL C-A/AP/146 (2004); Can be understood with combined electron and ion cloud – U. Iriso and S. Peggs, PRST-AB 9, 071002 (2006).]

# STAR: effect of TSP sublimation (Run-4 Au-Au 2004)

# Summary

- Experimental background is a continuing concern, has held back luminosity at times
- Main tool to reduce experimental background in RHIC is collimation (generally effective)
- Beam-gas background currently under control, may become a concern again with higher luminosity (addressed by vacuum upgrade when beam pipe is upgrade)
- Communication between experiments and machine on what is luminosity and background continues (a few true background signals from experiments extremely useful)

# Additional material

# Collimator upgrades: simulation

## Status:

RHIC aperture file complete

RHIC collimators imported into SixTrack

Loss maps available and are being compared

## Need to do:

Compare collimation efficiency

Add 2<sup>nd</sup> vertical collimators and compute efficiency from simulation

Install 2<sup>nd</sup> vertical collimators

Picture provided by G. Robert-Demolaize

Discrepancies are under investigation

## IR (DX-DX)

## Typical Layout of Experiment Regions

Stainless steel transition pipes  
on both sides (7cm $\Rightarrow$ 12cm)

### Brahms, Phenix, Star

1mm x 7.6cm  $\Phi$  Be brazed to Al or SS sections

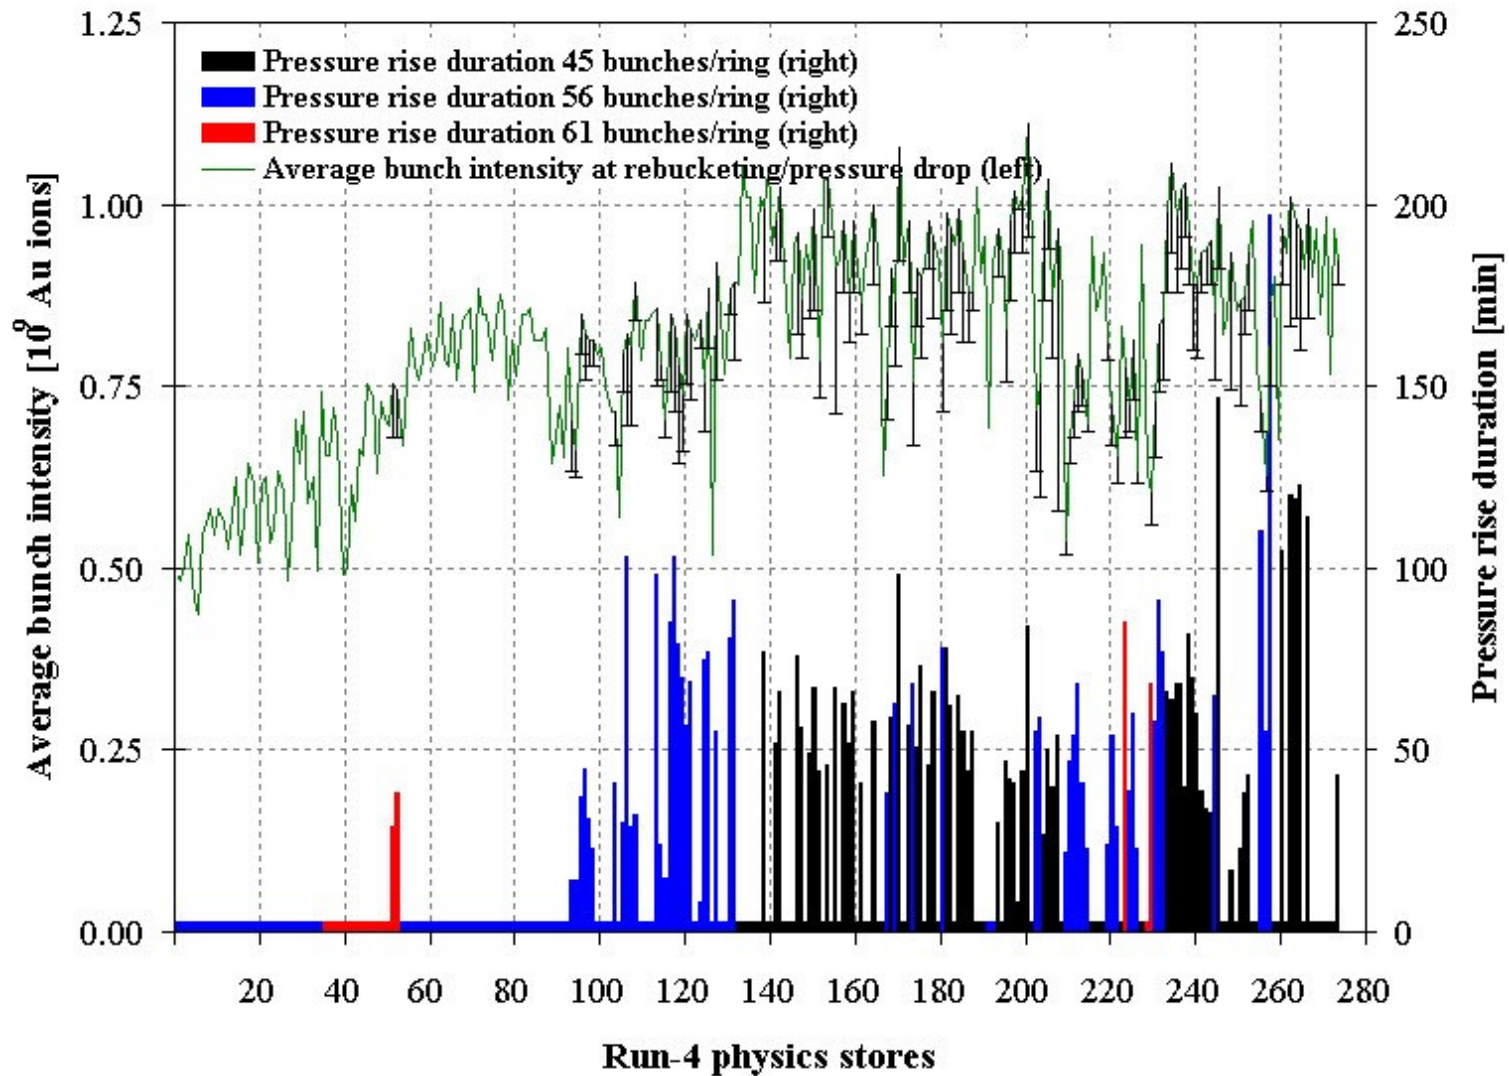

Install NEG coated Al  
sleeve 0.25mm thick?

Phobos: 3 x 4m long Be pipes with Be flanges and bolts

|                           | <u>Brahms</u> | <u>Phenix</u> | <u>Phobos</u> | <u>Star</u> |
|---------------------------|---------------|---------------|---------------|-------------|
| Central pipe L(m)         | 7.1           | 5.5           | 3 x 4         | 8.1         |
| Be section L(m)           | 1.5           | 1.5           | 3 x 4         | 1.5         |
| Brazed material           | Al            | St. st        |               | Al          |
| Bake Temp ( $^{\circ}$ C) | 150           | 200           | 200           | $\sim$ 100  |

# PHOBOS – Average bunch intensity at rebucketing/pressure drop, and duration of increased pressure sorted by bunch patterns

## Remote TSP sublimation at STAR – H.C. Hseuh, Run-4 Retreat

Titanium sublimation pumps (TSP) as main UHV pumps (+ ion pumps)

48A x 5min  $\approx$  10 mono-layers Ti on to  $\sim$  500 cm<sup>2</sup> pump surface

$\tau \sim 10^3$  sec @  $10^{-7}$  Torr;  $10^5$  sec @  $10^{-9}$  Torr;  $10^7$  sec @  $10^{-11}$  Torr

i.e. Booster: TSP sublimed about once per run

< 500 mg usable Ti per filament  $\approx$  <100 x 5min sublimation

Did periodical “manual” sublimations in Feb. and Mar. at IR6 and IR10

To help reduce  $\Delta P$

$\sim$  1 hour beam-off time: CH<sub>4</sub> release during sublimation (up to  $10^{-7}$  Torr)

$\sim$  tens minutes to pump away by ion pumps (and cold bore @Q3-Q4)

Need automated sublimation system

TSP power supplies are capable of remote operation

Need new software and control interface – done.
