

Dipole model analysis of high precision HERA data at low x

Henri Kowalski and Agnieszka Luszczak
DIS 2014, Warszawa
1st of May, 2014

Why low- x region is very interesting?

it is dominated by the gluon density,

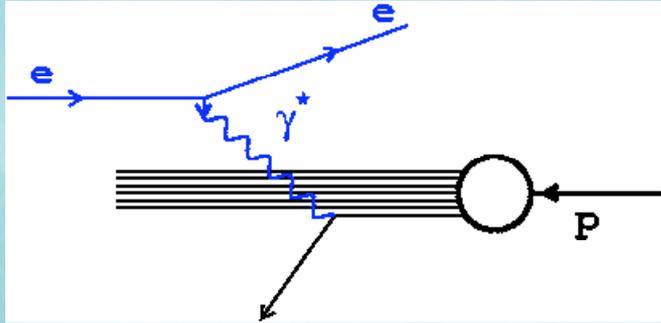

precise knowledge of gluon density is very important for LHC physics

- low- x region is a multi-regge region in which it is possible to sum up QCD Feynman diagrams to infinity (BFKL resummation)
 - it is the limit in which it is possible to evaluate N=4 QCD (gravitational diagrams) up to infinite order (Dixon, Bern, ...)
- ☞ could become a bridge to gravitation

It is a region with large amount of diffractive processes, dipole picture

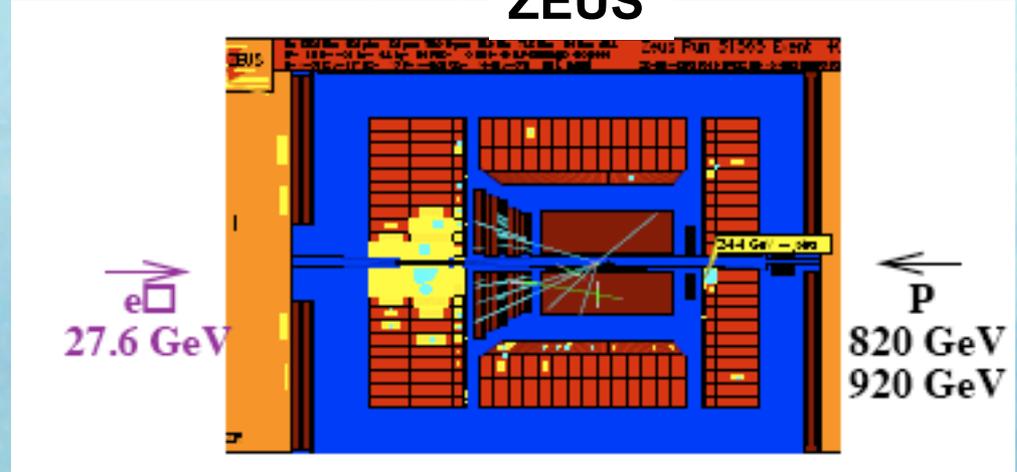

exclusive J/Psi, rho..... processes are new probes of matter

Inclusive Scattering

DIS at HERA at low x

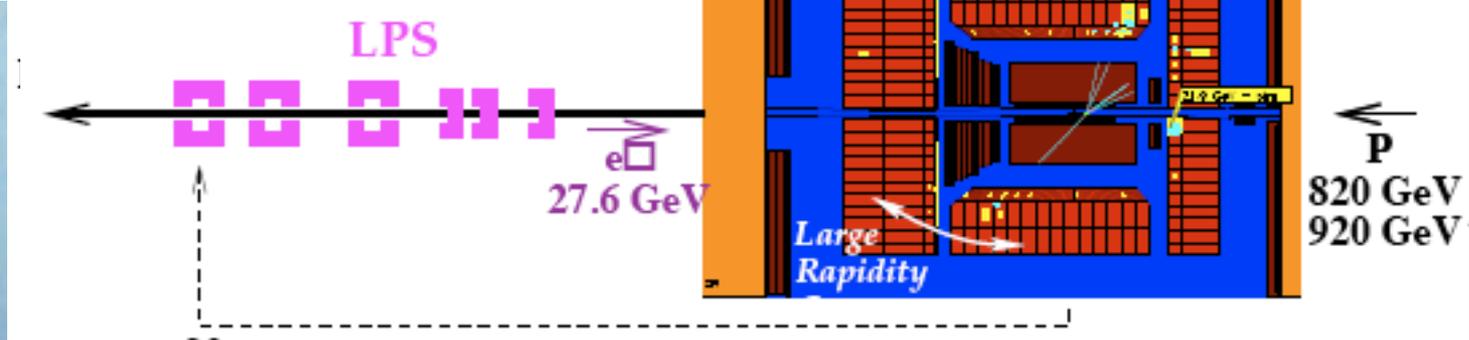

ZEUS

Diffractive Scattering

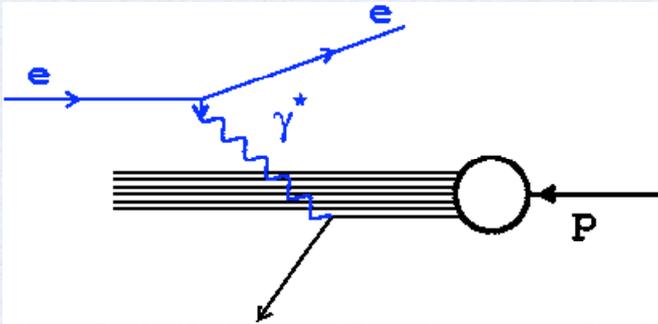

expectation before HERA
~ 0.01%

seen ~20% at $Q^2 = 4 \text{ GeV}^2$
~10% at $Q^2 = 20 \text{ GeV}^2$

Partons vs Dipoles at low- x

Infinite momentum frame: Partons

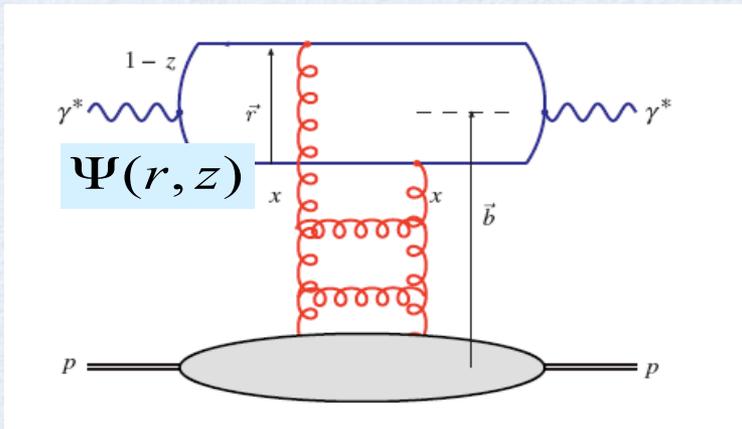

F_2 measures parton density at a scale Q^2

$$F_2 = \sum_f e_f^2 xq(x, Q^2)$$

Proton rest frame: Dipoles - long living quark pair interacts with the gluons of the proton

dipole life time $\approx 1/(m_p x)$

$= 10 - 1000 \text{ fm at } x = 10^{-2} - 10^{-4}$

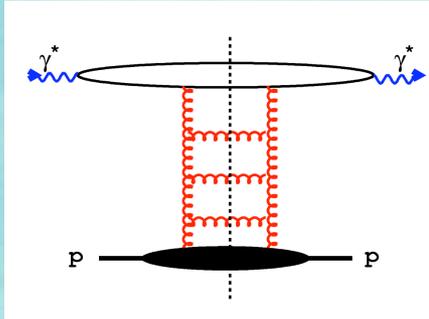

$$\sigma_{tot}^{\gamma^* p} = \int \Psi^* \sigma_{qq} \Psi ; \quad F_2 = \frac{Q^2}{4\pi^2 \alpha_{em}} \sigma_{tot}^{\gamma^* p}$$

for small dipoles, at low- x , dipole picture is equivalent to the QCD parton picture

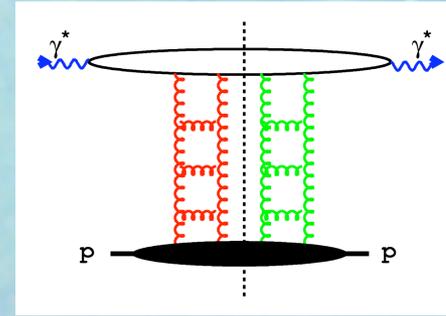

$$\sigma_{qq} \sim r^2 xg(x, Q^2)$$

Low-x phenomena in DIS give access to the properties of the gluon density

- rise of F2 with decreasing x
- diffractive reactions

← Optical Theorem →

$$\sigma_{tot}^{\gamma^* p} = \int \Psi^* \sigma_{qq} \Psi$$

$$\frac{d\sigma^{\gamma^* p \rightarrow V p}}{dt} \sim \left| \int d^2b \Psi_V^* \Psi e^{-i\vec{b} \cdot \vec{\Delta}} \frac{d\sigma_{q\bar{q}}}{d^2b} \right|^2$$

$$\frac{d\sigma_{q\bar{q}}}{d^2b} \sim r^2 \alpha_s x g(x, \mu^2) T(b) \quad \text{for small dipole size}$$

The same, universal, gluon density describes the properties of many reactions: F_2 , F_L , inclusive diffraction, exclusive J/Psi, Phi and Rho production, DVCS, diffractive jets

Determination of Gluon Density in pdf's

GD is determined from the increase of F_2 with x and Q^2 in low- x region

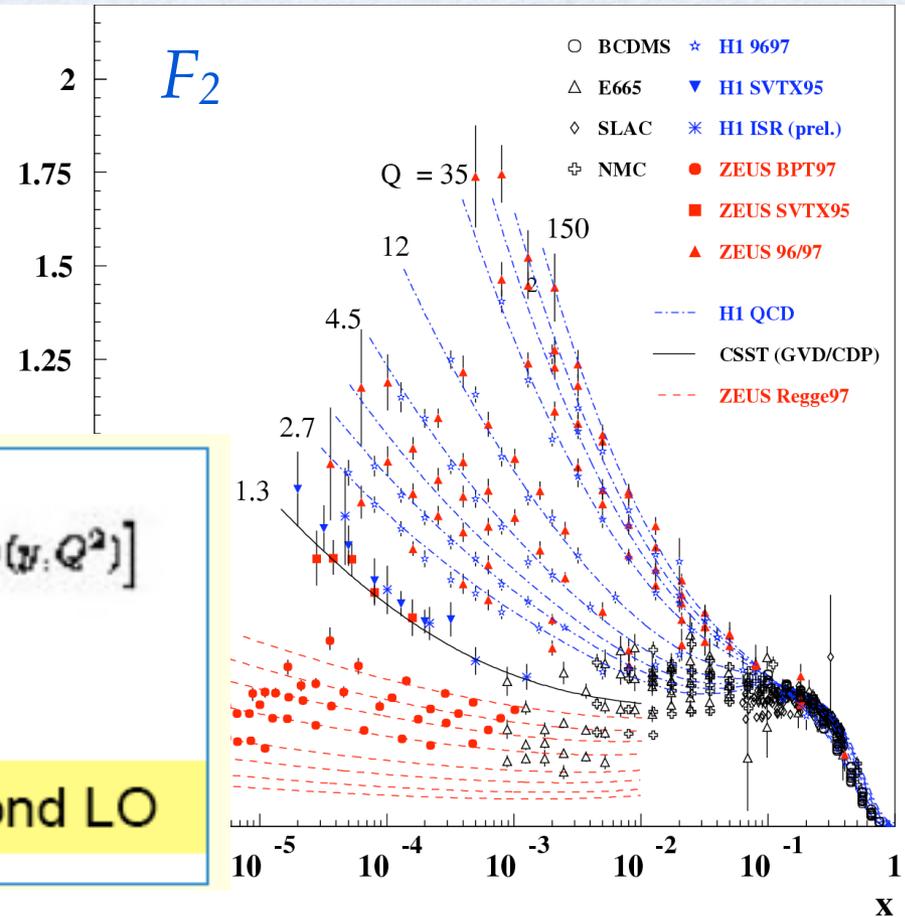

Determine pdf's densities from the χ^2 fit to the data

$$\frac{F_2(x, Q^2)}{x} = \int_0^1 \frac{dy}{y} \left[\sum_i C_2(z, \alpha_s) q_i(x, Q^2) + C_g(z, \alpha_s) g(y, Q^2) \right]$$

$$C_2(z, \alpha_s) = e_s^2 [\delta(1-z) + \alpha_s f_2(z)]$$

$$C_g(z, \alpha_s) = \alpha_s f_g(z)$$

beyond LO

Who? ABM, MSTW, CT(EQ), HERAPDF, (G)JR, NNPDF

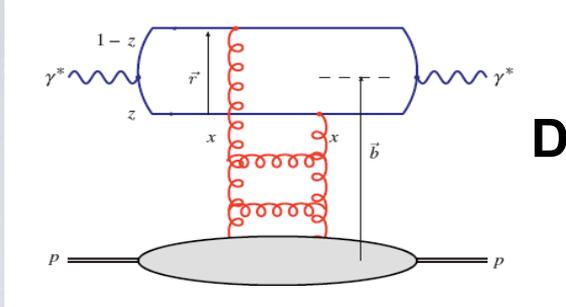

How? Start from parametrized form of $g(q)(x, Q_0^2)$ at Q_0^2 1-7 GeV^2
use N(N)LO DGLAP, MSbar factorisation, Heavy quark scheme

Dipole model analysis of high precision HERA data

A. Luszczak¹, H. Kowalski²

published in PRD

Data: HERA I combined inclusive DIS measurement

Dipole model is valid in the low- x limit ($x < 0.01$) where the valence quark contribution is small ($\sim 5\%$) and describes the sea-quark or gluon density contribution to F_2

precision of the measurements: $\sim 2\%$ in the low- x region

For a full description one has to take the contribution of the valence quarks into account

$$\sigma^{\gamma p} = \frac{4\pi^2 \alpha_{em}}{Q^2} F_2 = \sum_f \int d^2 r \int_0^1 dz |\Psi^\gamma(r, z, Q^2, m_f)|^2 \hat{\sigma}(r, x)$$

Dipole cross section

- BGK (Bartels-Golec-Kowalski) parametrization

$$\hat{\sigma}(r, x) = \sigma_0 \left\{ 1 - \exp \left[-\pi^2 r^2 \alpha_s(\mu^2) x g(x, \mu^2) / (3\sigma_0) \right] \right\}$$

- $\mu^2 = C/r^2 + \mu_0^2$ is the scale of the gluon density
- μ_0^2 is a starting scale of the QCD evolution. $\mu_0^2 = Q_0^2$
- gluon density is evolved according to the LO or NLO DGLAP eq.
- soft gluon:

$$xg(x, \mu_0^2) = A_g x^{\lambda_g} (1-x)^{C_g}$$

- soft + hard gluon:

$$xg(x, \mu_0^2) = A_g x^{\lambda_g} (1-x)^{C_g} (1 + D_g x + E_g x^2)$$

- soft + negative gluon:

$$xg(x, \mu_0^2) = A_g x^{\lambda_g} (1-x)^{C_g} - A'_g x^{\lambda'_g} (1-x)^{C'_g}$$

BGK (NLO) + valence quarks (soft gluon)

● “soft gluon”: $xg(x, \mu_0^2) = A_g x^{\lambda_g} (1-x)^{C_g}$

● “soft + hard gluon”: $xg(x, \mu_0^2) = A_g x^{\lambda_g} (1-x)^{C_g} (1 + D_g x + E_g x^2)$

Comparison of the gluon density determined with the soft and soft+hard assumptions

fixed valence q .

fitted valence q .

Discussion of fits

The precise HERA data can be very well described by the kT factorized, DGLAP evolved, gluon density evaluated within the (BGK) dipole model

Valence quark contribution added to the dipole model (BGK) improve the fits significantly ($\chi^2 \searrow$) in comparison to fits with the pure dipole contribution

Large improvement of fit quality is observed when Q^2 cut is increased from 3.5 GeV^2 to 8.5 GeV^2 for both dipole and pdf fits.

- ▶ NNLO effects? (presumably not)
- ▶ saturation effects up to higher Q^2 ? (presumably not)
- ▶ some modification of the standard QCD evolution ?

CONCLUSIONS

study of the low- x region remains
experimentally (x up to 10^{-6} at LHC)
and theoretically
very interesting

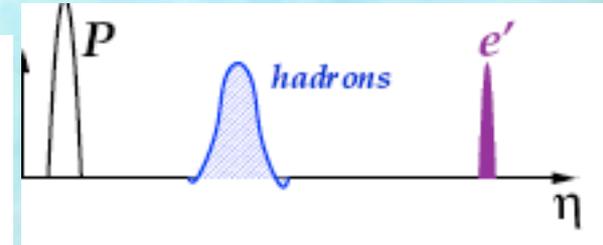

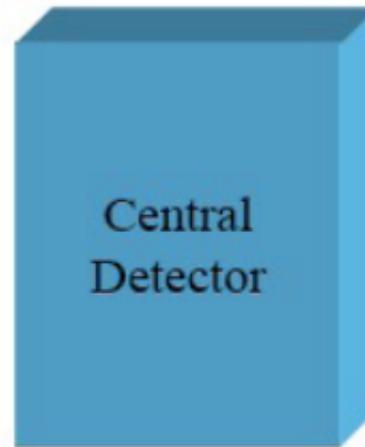

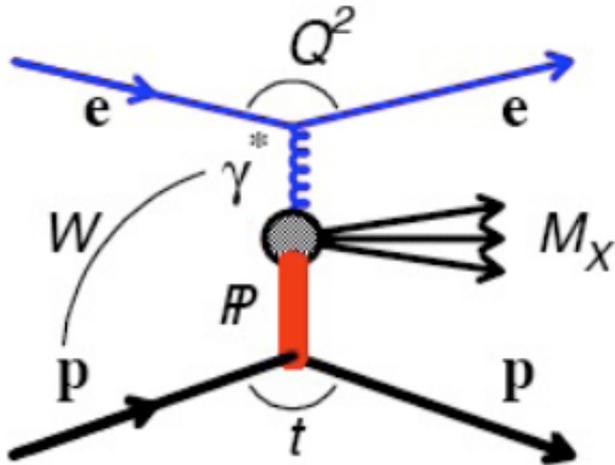

Back up

Note that:

The degree of saturation is characterized by the size of the dipole, r_s , which starts to interact multiple times (in $\sim 60\%$ of cases). At HERA, $Q_s^2 = 2/r_s^2 \sim 1 \text{ GeV}^2$ at $x = 10^{-4}$

► to avoid saturation effect on few % level Q^2 cut should be by an order of magnitude higher than the saturation scale

DIS Reactions

Rapidity Gaps
 $\Delta Y = \ln(W^2/M_X^2) \approx \Delta\eta$

Forward protons
 with $x_L = 1 - x_{IP} > 95\%$
 $x_L \sim$ longitudinal fraction of proton momentum

Inclusive variables:

Q^2 - virtuality of the incoming photon

W - CMS energy of the incoming photon-proton system

x - $\approx Q^2 / W^2$

Diffractive variables:

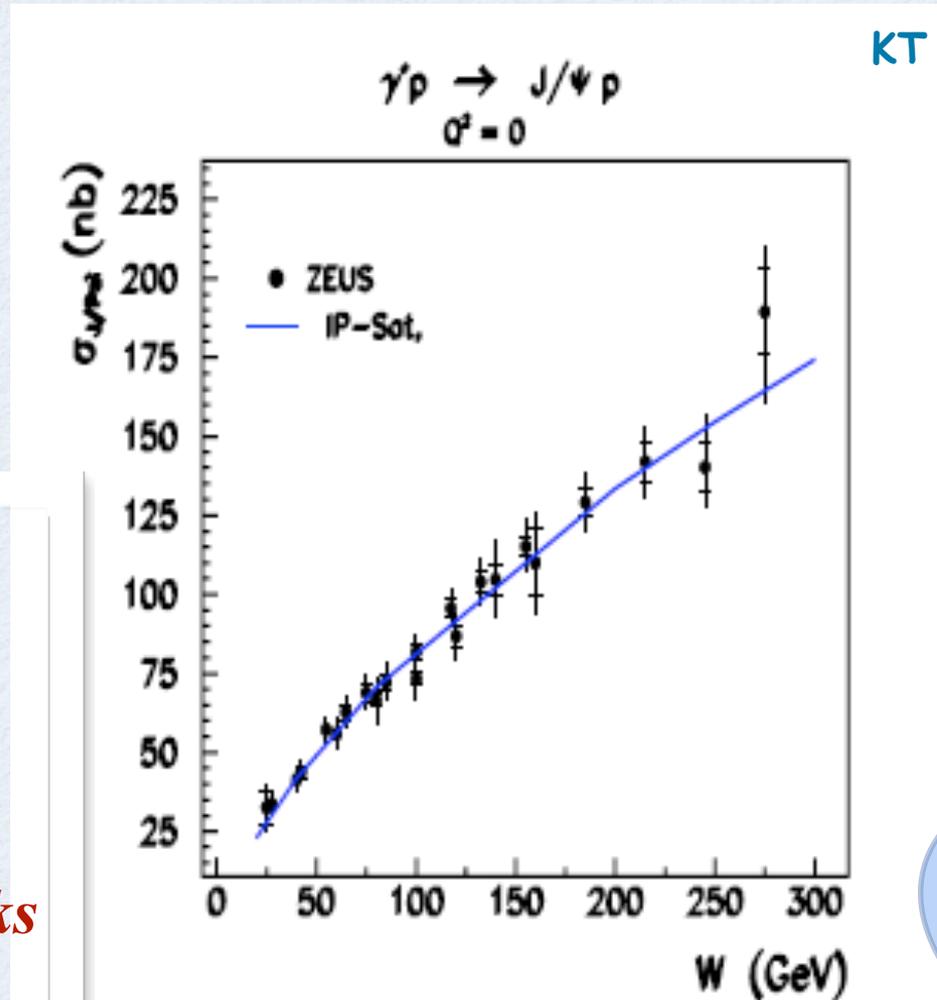

M_X - invariant mass of all particles seen in the detector

t - momentum transfer to the diffractively scattered proton

Exclusive J/psi production

educated guess
for VM wf is
working very well
for J/psi and phi
and DVCS

Note:
J/psi x-section
grows almost
like
 $\sigma \propto (x g(x, \mu^2))^2$
no valence quarks
contribution

equally good
description of
 Q^2 and σ_L/σ_T
dependences
for J/psi and phi
and DVCS

new,
precise
H1 data

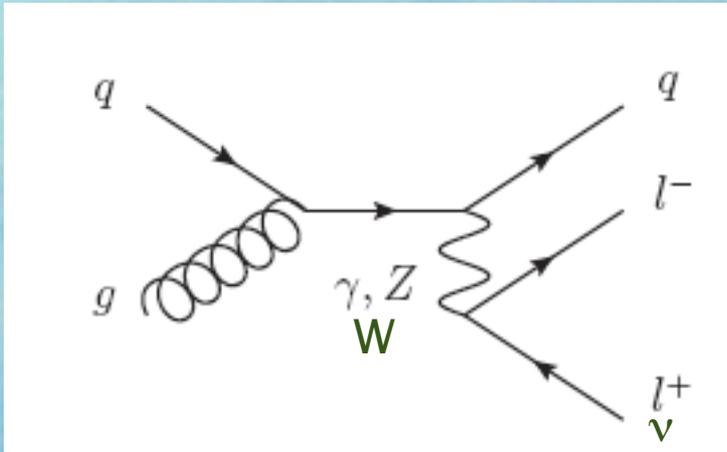

➤ the determination of gluon density with J/psi would be more precise than by F_2 or F_L (MRT) **if J/psi would have small systematic errors**

DATA

DIS (HERA and fixed target..), Drell-Yan processes (fixed target)
 High E_T jets (Tevatron), W,Z rapidity (Tevatron)
 νN dimuon (CCFR, NuteV)....

HERAPDF 1.0 uses combined H1 and ZEUS HERA I xs data
 HERAPDF 1.5 uses, in addition, combined HERA charm data ..

Excellent test reaction
 W, Z production at LHC

W, Z production at LHC is
 a low-x effect
