A Fixed-Target ExpeRiment at the LHC

April 29, 2014 2 / 29

#### Decisive advantages of Fixed-target experiments

 Fixed-target experiments offer specific advantages that are still nowadays difficult to challenge by collider experiments

### Decisive advantages of Fixed-target experiments

- Fixed-target experiments offer specific **advantages** that are still nowadays **difficult to challenge by collider experiments**
- They exhibit 4 decisive features,
  - accessing the high Feynman  $x_F$  domain ( $x_F \equiv \frac{p_z}{p_{z_{max}}}$ )
  - achieving high luminosities with dense targets,
  - varying the atomic mass of the target almost at will,
  - polarising the target.

[Rapidity shift:  $\Delta y = tanh^{-1}\beta \simeq 4.8$ ]

• The entire forward CM hemisphere ( $y_{CM} > 0$ ) within  $0^{\circ} \le \theta_{Lab} \le 1^{\circ}$ [ $y_{CM} = 0 \Rightarrow y_{Lab} \simeq 4.8$ ]

• pp or pA collisions with a 7 TeV  $p^+$  on a fixed target occur at a CM energy

 $\sqrt{s} = \sqrt{2m_N E_p} \simeq 115 \, \mathrm{GeV}$ 

- In a symmetric collider mode,  $\sqrt{s} = 2E_{\rho}$ , *i.e.* much larger
- Benefit of the fixed target mode : boost:  $\gamma_{CM}^{Lab} = \frac{\sqrt{s}}{2m_{\rho}} \simeq 60$ 
  - Consider a photon emitted at 90° w.r.t. the z-axis (beam) in the CM:
  - $\begin{pmatrix} E_{Lab} \\ p_{z,Lab} \end{pmatrix} = \begin{pmatrix} \gamma & \gamma \beta \\ \gamma \beta & \gamma \end{pmatrix} \begin{pmatrix} p_T \\ 0 \end{pmatrix}$   $(p_{z,CM} = 0, E_{CM}^{\gamma} = p_T)$
  - $p_{z,Lab} \simeq 60 p_T$  ! [A 67 MeV  $\gamma$  from a  $\pi^0$  at rest in the CM can easily be detected.]
- Angle in the Lab. frame:  $\tan \theta = \frac{p_T}{p_{Z,Lab}} = \frac{1}{\gamma\beta} \Rightarrow \theta \simeq 1^\circ$ .

[Rapidity shift:  $\Delta y = tanh^{-1}\beta \simeq 4.8$ ]

• The entire forward CM hemisphere ( $y_{CM} > 0$ ) within  $0^{\circ} \le \theta_{Lab} \le 1^{\circ}$ 

 $[y_{CM}\,{=}\,0 \Rightarrow y_{Lab}\,{\simeq}\,4.8]$ 

- Good thing: small forward detector  $\equiv$  large acceptance
- Bad thing: high multiplicity  $\Rightarrow$  absorber  $\Rightarrow$  physics limitation

• Let's adopt a novel strategy and look at larger angles

- Let's adopt a novel strategy and look at larger angles
- Advantages:
  - $\cdot$  reduced multiplicities at large(r) angles
  - $\cdot$  access to partons with momentum fraction  $x \rightarrow 1$  in the target
  - · last, but not least, the beam pipe is in practice

not a geometrical constrain at  $\theta_{CM} \simeq 180^{\circ}$

### Conclusion

• Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments

< 6 b

- Both p and Pb LHC beams can be extracted without disturbing the other experiments
   Extraction a few per cent of the beam of Ext 10<sup>8</sup> protono per cent
- Extracting a few per cent of the beam  $\rightarrow 5 \times 10^8$  protons per sec

- Both p and Pb LHC beams can be extracted without disturbing the other experiments
   Extraction a few per cent of the beam of Ex 10<sup>8</sup> pretons per cent
- Extracting a few per cent of the beam  $\rightarrow 5 \times 10^8$  protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at  $\sqrt{s} = 115 \text{ GeV}$  and  $\sqrt{s_{NN}} = 72 \text{ GeV}$

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam  $\rightarrow 5 \times 10^8$  protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at  $\sqrt{s} = 115 \text{ GeV}$  and  $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam  $\rightarrow 5 \times 10^8$  protons per sec
- This allows for high luminosity pp, pA and PbA collisions at  $\sqrt{s} = 115 \text{ GeV}$  and  $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of
  - high luminosity (reach in y,  $P_T$ , small BR channels)
  - target versatility (nuclear effects, strongly limited at colliders)
  - modern detection techniques (e.g.  $\gamma$  detection with high multiplicity)

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam  $\rightarrow 5 \times 10^8$  protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at  $\sqrt{s} = 115 \text{ GeV}$  and  $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of
  - high luminosity (reach in y,  $P_T$ , small BR channels)
  - target versatility (nuclear effects, strongly limited at colliders)
  - modern detection techniques (e.g.  $\gamma$  detection with high multiplicity)
- This would likely prepare the ground for  $g(x, Q^2)$  extraction

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments
- Extracting a few per cent of the beam  $\rightarrow 5 \times 10^8$  protons per sec
- This allows for high luminosity *pp*, *pA* and *PbA* collisions at  $\sqrt{s} = 115 \text{ GeV}$  and  $\sqrt{s_{NN}} = 72 \text{ GeV}$
- Example: precision quarkonium studies taking advantage of
  - high luminosity (reach in y,  $P_T$ , small BR channels)
  - target versatility (nuclear effects, strongly limited at colliders)
  - modern detection techniques (e.g.  $\gamma$  detection with high multiplicity)
- This would likely prepare the ground for  $g(x, Q^2)$  extraction
- A wealth of possible measurements:
   DY, Open b/c, jet correlation, UPC... (not mentioning secondary beams)

- Both *p* and *Pb* LHC beams can be extracted without disturbing the other experiments

æ

#### • Inter-crystalline fields are huge

• The channeling efficiency is high for a deflection of a few mrad

J.P. Lansberg (IPNO, Paris-Sud U.) A Fixed-Target ExpeRiment at the LHC April 29, 2014

4 6 1 1 4

31/29

•

The channeling efficiency is high for a deflection of a few mrad
One can extract a significant part of the beam loss (10<sup>9</sup>p<sup>+</sup>s<sup>-1</sup>)

< 6 b

- The channeling efficiency is high for a deflection of a few mrad
- One can extract a significant part of the beam loss  $(10^9 p^+ s^{-1})$
- Simple and robust way to extract the most energetic beam ever:

#### Beam extraction

#### • Beam extraction @ LHC

... there are extremely promising possibilities to extract 7 TeV protons from the circulating beam by means of a bent crystal.

••• The idea is to put a bent, single crystal of either Si or Ge (W would perform slightly better but needs substantial improvements in crystal quality) at a distance of  $\simeq 7\sigma$  to the beam where it can intercept and deflect part of the beam halo by an angle similar to the one the foreseen dump kicking system will apply to the circulating beam.

... ions with the same momentum per charge as protons are deflected in a crystal with similar efficiencies

If the crystal is positioned at the kicking section, the whole dump system can be used for slow extraction of parts of the beam halo, the particles that are anyway lost subsequently at collimators.

- Beam loss: 10<sup>9</sup> p<sup>+</sup>s<sup>-1</sup>
- Extracted intensity:  $5 \times 10^8 \ p^+ s^{-1}$  (1/2 the beam loss) E. Uggerhoj, UJ Uggerhoj, NIM B 234 (2005) 31

- Beam loss: 10<sup>9</sup> p<sup>+</sup>s<sup>-1</sup>
- Extracted intensity:  $5 \times 10^8 \ p^+ s^{-1}$  (1/2 the beam loss) E. Uggerhej, UJ Uggerhej, NIM B 234 (2005) 31
- Number of  $p^+$ : 2808 bunches of  $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$

- Beam loss: 10<sup>9</sup> p<sup>+</sup>s<sup>-1</sup>
- Extracted intensity:  $5 imes 10^8~p^+ {
  m s}^{-1}$  (1/2 the beam loss) E. Uggerhoj, UJ Uggerhoj, NIM B 234 (2005) 31
- Number of  $p^+$ : 2808 bunches of  $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of  $3.10^5 \text{ km.s}^{-1}/27 \text{ km} \simeq 11 \text{ kHz}$

#### Backup slides

### A few figures on the (extracted) proton beam

- Beam loss: 10<sup>9</sup> p<sup>+</sup>s<sup>-1</sup>
- Extracted intensity:  $5 imes 10^8 \ p^+ {
  m s}^{-1}$  (1/2 the beam loss) E. Uggerhoj, UJ Uggerhoj, NIM B 234 (2005) 31
- Number of  $p^+$ : 2808 bunches of  $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of  $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
  - $\bullet~$  the crystal sees  $2808 \times 11000~s^{-1} \simeq 3.10^7$  bunches  $s^{-1}$
  - one extracts  $5.10^8/3.10^7 \simeq 15p^+$  from each bunch at each pass
  - Provided that the probability of interaction with the target is below 5%,

no pile-up !

- Beam loss: 10<sup>9</sup> p<sup>+</sup>s<sup>-1</sup>
- Extracted intensity:  $5 \times 10^8 \ p^+ s^{-1}$  (1/2 the beam loss) E. Uggerhoj, UJ Uggerhoj, NIM B 234 (2005) 31
- Number of  $p^+$ : 2808 bunches of  $1.15 \times 10^{11} p^+ = 3.2 \times 10^{14} p^+$
- Revolution frequency: Each bunch passes the extraction point at a rate of  $3.10^5~km.s^{-1}/27~km\simeq 11~kHz$
- Extracted "mini" bunches:
  - $\bullet~$  the crystal sees  $2808 \times 11000~s^{-1} \simeq 3.10^7$  bunches  $s^{-1}$
  - one extracts  $5.10^8/3.10^7 \simeq 15p^+$  from each bunch at each pass
  - Provided that the probability of interaction with the target is below 5%,
- Extraction over a 10h fill:
  - $5 \times 10^8 p^+ \times 3600 \text{ s } \text{h}^{-1} \times 10 \text{ h} = 1.8 \times 10^{13} p^+ \text{ fill}^{-1}$
  - This means  $1.8 \times 10^{13}/3.2 \times 10^{14} \simeq 5.6\%$  of the  $p^+$  in the beam

These protons are lost anyway !

no pile-up !

- Beam loss: 10<sup>9</sup> p<sup>+</sup>s<sup>-1</sup>
- Extracted intensity:  $5 \times 10^8 \ p^+ s^{-1}$  (1/2 the beam loss) E. Uggerhej, UJ Uggerhej, NIM B 234 (2005) 31

Simone Montesano - February 11th, 2013 - Physics at AFTER using the LHC beams

#### Crystal resistance to irradiation

- IHEP U-70 (Biryukov et al, NIMB 234, 23-30):
  - 70 GeV protons, 50 ms spills of 10<sup>14</sup> protons every 9.6 s, several minutes irradiation
  - equivalent to 2 nominal LHC bunches for 500 turns every 10 s
  - · 5 mm silicon crystal, channeling efficiency unchanged
- · SPS North Area NA48 (Biino et al, CERN-SL-96-30-EA):
  - 450 GeV protons, 2.4 s spill of 5 x 10<sup>12</sup> protons every 14.4 s, one year irradiation, 2.4 x 10<sup>20</sup> protons/cm<sup>2</sup> in total,
  - · equivalent to several year of operation for a primary collimator in LHC
  - 10 x 50 x 0.9 mm<sup>3</sup> silicon crystal, 0.8 x 0.3 mm<sup>2</sup> area irradiated, channeling efficiency reduced by 30%.
- HRMT16-UA9CRY (HiRadMat facility, November 2012):
  - 440 GeV protons, up to 288 bunches in 7.2 µs, 1.1 x 10<sup>11</sup> protons per bunch (3 x 10<sup>13</sup> protons in total)
  - · energy deposition comparable to an asynchronous beam dump in LHC
  - 3 mm long silicon crystal, no damage to the crystal after accurate visual inspection, more tests planned to assess possible crystal lattice damage
    - · accurate FLUKA simulation of energy deposition and residual dose

### The lead-ion beam

- Design LHC lead-beam energy: 2.76 TeV per nucleon
- In the fixed target mode, PbA collisions at  $\sqrt{s_{NN}} \simeq 72 \text{ GeV}$
- Half way between BNL-RHIC (AuAu, CuCu @ 200 GeV) and CERN-SPS (PbPb @ 17.2 GeV)
- Example of motivations:

Fig. 7. Measured J/ψ production yields, normalised to the yields expected assuming that the only source of suppression is the ordinary absorption by the nuclear medium. The data is shown as a function of the energy density reached in the several collision systems.

W. J. Stirling

Department of Physics, University of Durham, Durham, England (Received 27 July 1987)

We perform a next-to-leading-order structure-function analysis of deep-inelastic  $\mu N$  and  $\nu N$ scattering data and find acceptable fits for a range of input gluon distributions. We show three equally acceptable sets of parton distributions which correspond to gluon distributions which are (1)  $\nu cohr, '12)$  hard(-m) and (3) which behaves as  $\sigma(X) - 1/\sqrt{x}$  at small x.  $J/\phi$  and promph hoton hadroproduction data are used to discriminate between the three sets. Set 1, with the "soft"-gluon distribution, is favored. W, Z, and gir production data from the CERN collider are well described but do not distinguish between the sets of structure functions. The precision of the predictions for  $\sigma u$ directly measured to Dilder are well described but do may a soft the collider measurements to yield information on the number of light neutrinos and the mass of the top quark. Finally we discuss how the gluon distribution at very small x may be directly measured at DESY HERA.

Production puzzle → quarkonium not used anymore in global fits
With systematic studies, one would restore its status as gluon probe

#### LHB, a fixed target experiment at LHC to measure CP violation in B mesons Flavio Costantini

University of Pisa and INFN. Italy

A fixed target experiment at LHC to measure CP violation in B mesons is presented. A description of the proposed apparatus is given together with its sensitivity on the CP violation asymmetry measurement for the two benchmark decay channels  $B^0 \rightarrow J/\psi +$  $K_{e}^{0}, B^{0} \rightarrow \pi^{+} \pi^{-}$ . The possibility of obtaining an extracted LHC beam hinges on channeling in a bent silicon crystal. Recent results on beam extraction efficiencies measured at CERN SPS based on this technique are presented.

#### 1. Introduction

•••

This paper presents a fixed target experiment to measure CP violation in the B system based on the possibility of extracting the 8 TeV LHC proton beam using a bent silicon crystal [4]. A 10% extraction efficiency of the LHC beam halo will give an extracted beam intensity of about 10<sup>8</sup> protons/s allowing the production of as many as 10<sup>10</sup> BB pairs per year, i.e. about two orders of magnitude more than what could be produced by an e<sup>+</sup>e<sup>-</sup> asymmetric B factory with  $10^{34}$  cm<sup>-3</sup>s<sup>-1</sup> luminosity [5].

## Isolated- $\gamma$ in p(7 TeV)-p(rest): $\sqrt{s} \sim 115$ GeV

■ p-p photon kinematics at fixed-target LHC (central rapidities): To access x > 0.3 one needs isolated- $\gamma$  at:  $p_{\tau} = x_{\tau} \sqrt{s/2} > 20$  GeV/c

J.P. Lansberg (IPNO, Paris-Sud U.)

A Fixed-Target ExpeRiment at the LHC
