Beyond Standard Model Physics in Herwig++

Martyn Gigg

IPPP, Durham University

MCnet meeting, Lund, January 2008
Created method enabling the implementation of new physics models in Herwig++ easier.

1. MatrixElement and Decayer classes based on external spins;
2. Vertex classes encode Feynman rules that are used in the calculation of amplitudes through HELAS formalism.

Implementation of a new model requires only a set of Feynman rules and specification of any new particles.

Details can be found in hep-ph/0703199.
Current Release

- As of Herwig++ 2.1, BSM physics is included for the first time
- Release includes:
  - Minimal Supersymmetric Standard Model (CP and flavour conserving),
  - Minimal Universal Extra Dimensions,
  - Randall-Sundrum.

Spin correlations included in $2 \rightarrow 2$ production matrix elements and $1 \rightarrow 2$ decay matrix elements.
Minimal Supersymmetric Standard Model

\[ \tilde{q}_L \rightarrow q, \tilde{\chi}_2^0 \rightarrow \tilde{l}_R, q, l^\pm \rightarrow q, l^\pm, l^\mp \tilde{\chi}_{10} \]
Minimal Universal Extra Dimensions, N=1

\[ q^* \rightarrow q, Z_1^* \rightarrow l^*, q, l^\pm \rightarrow q, l^\pm, l^\mp \gamma_1^* \]

A contribution to the Les Houches 2007 proceedings, with Pedro Ribeiro of CMS, on the subject of the discovery potential of MUED at CMS and discrimination against SUSY.
Off-shell Effects

We don’t want to limit ourselves to on-shell cascades of BSM particles, want to incorporate off-shell effects as well.

When a particle is produced its mass is generated according to a Breit-Wigner,

\[
\int dm^2 \frac{m \Gamma(m)}{(m^2 - M^2)^2 + m^2 \Gamma(m)^2}
\]

and the running width \(\Gamma(m)\) is calculated using the Decayer classes.
The NMSSM is an extension of the MSSM which is mainly motivated to solve the so-called $\mu$ problem of the MSSM. The MSSM superpotential has to contain a term like
\[ \mu H_1 H_2 \]
but $\mu$ is not “naturally” of the order of the EW scale as it should be phenomenologically.

The NMSSM solves this problem by adding an extra Higgs singlet field $N$. The $\mu$ term is then dynamically generated when this field acquires a VEV giving $\mu = \lambda \langle N \rangle$. 
The particle content of the NMSSM is that of the MSSM with the addition of a CP-even and CP-odd Higgs and a fifth neutralino.

This introduces 2 Higgs mixing matrices one for the CP-even and one for the CP-odd sector and the neutralino mixing matrix becomes $5 \times 5$.

Implementation of the model simply requires replacing those vertices in the MSSM that contain a Higgs particle with the NMSSM counterpart.

The model is now implemented in Herwig++. 
Current release includes BSM physics; MSSM, MUED and RS Model,
Also possible to simulate off-shell effects while using two body decayers,
NMSSM has been implemented, Little Higgs hot on its tail.
