

POOL Token Scatterer

**Peter VanGemmeren (ANL)
Kenny Umenthum (Summer Student @ ANL)
Vakho Tsulaia (LBNL)**

**Event Service Phone Meeting
August 30th, 2013**

Reader Processes for AthenaMP

- Peter developed first implementation of an I/O worker process for AthenaMP two years ago: **Shared RAW Reader**
 - Implemented as an AlgTool: **ByteStreamSharedMemoryTool**
 - Works only for ByteStream format
 - **Reader sends event data to the event processors via shared memory segment**
 - **Event data: raw buffer void***
 - For more details see Peter's presentation at S&C Week in October 2011
- Next step: extend the existing mechanism for working with POOL files
 - Reader process sends event POOL tokens (`string`) to the worker processes
 - **After receiving the token, the worker process reads event data either from local file or from remote file (using ROOT mechanisms for remote file access: TWebFile, TNetFile)**

New code

- **IAthenaIPCTool** (*New*). Abstract interface for AlgTools implementing shared reader mechanism
 - Lives in AthenaKernel, already in dev/devval
- Updated **EventSelectorAthenaPool**.
 - In dev/devval
- **AthenaSharedMemoryTool** (*New*). Reader process communicates with event processors via Shared Memory segment
 - Lives in AthenaServices. In SVN, not yet in dev/devval
- **AthenaYamplTool** (*New*). Reader process communicates with event processors via Yampl channel
 - Not yet in SVN. Will be added to AthenaServices

Extensions to AthenaMP-2

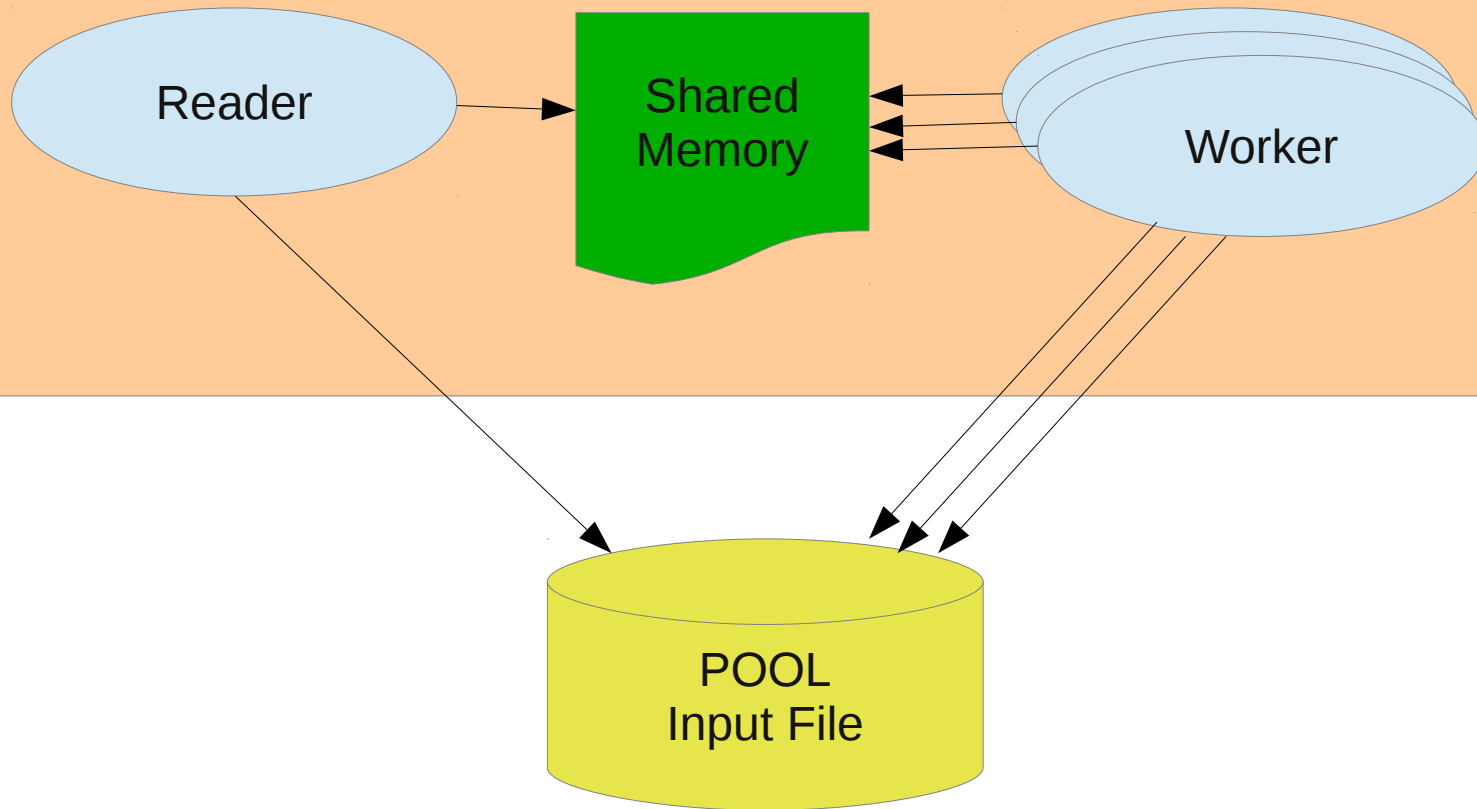

- Modify the existing SharedBSReader strategy
 - Rename it with **SharedReader**
 - Will run either over ByteStream or over POOL inputs
 - A quick comparison of single particle simulation outputs made with the Shared POOL Reader and with the default AthenaMP strategy (Shared Queue) showed no differences between them!

- Develop new **TokenScatterer** strategy to be used in the context of the **Event Service**
 - The Scatterer process gets event tokens from an external source (Yampl channel) and sends them over to the workers
 - **Workers read input events from remote ROOT file**

POOL Token Scatterer

Yampl implementation

AthenaMP

POOL Token Scatterer

- The first implementation exists
 - Developed quickly for this meeting, rather dirty
 - Not in SVN yet
 - The Scatterer process reads POOL tokens from an ASCII file
 - Workers read event data from remote file over **http:**
 - Have not tried **root:.** Do we need it? Will require dealing with rootd server, authentication, etc.
 - Needs to have a special entry for the input file in the PoolFileCatalog.xml on the worker node indicating the access protocol
- This mechanism was successfully tested by running a sample AtlasG4_tf job (single particle)
 - The job needs to have some input file at startup
 - For this purpose an one-event file was extracted from the input EVNT file.
 - **The remote reading worked as expected!**
 - And the outputs of this job were identical to the outputs obtained with local reading of the EVNT file

POOL Token Scatterer

Summary

- First implementation of the POOL Token Scatterer strategy for AthenaMP exists and is functional
- In order to to run with the Token Scatterer strategy AthenaMP requires
 1. An one-event input file for startup
 - We need to check what needs to be done in order to lift this restriction at least for simulation jobs
 2. A special entry in the local PoolFileCatalog for accessing events in the remote input file
 - With file location and the access protocol: either **http** or **root**
