What have we learned from angular correlation studies in p–Pb collisions?

Wednesday 15 January 2014 11:20 (35 minutes)

Angular correlations have been used extensively in heavy-ion collisions to probe the transport properties of the system. Similar studies in p–Pb collisions have recently revealed intriguing features, surprisingly similar to the heavy-ion results. In this talk, I will review the latest results from the analysis of the p–Pb run of 2013 on charged and identified particle correlations obtained with the ALICE detector at the LHC, and I will discuss their implications.
