

# Cosmic-ray research with AMS-02 on the International Space Station

Henning Gast  
RWTH Aachen

## PHYSICS

# The Space Station's Crown Jewel

A fancy cosmic-ray detector, the Alpha Magnetic Spectrometer, is about to scan the cosmos for dark matter, antimatter and more

By George Musser, staff editor

**T**HE WORLD'S MOST ADVANCED COSMIC-RAY DETECTOR TOOK 16 YEARS AND \$2 billion to build, and not long ago it looked as though it would wind up mothballed in some warehouse. NASA, directed to finish building the space station and retire the space shuttle by the end of 2010, said it simply did not have room in its schedule to launch the instrument anymore. Saving it took a lobbying campaign by physicists and intervention by Congress to extend the shuttle program. And so the shuttle *Endeavour* is scheduled to take off on April 19 for the express purpose of delivering the Alpha Magnetic Spectrometer (AMS) to the International Space Station.

Cosmic rays are subatomic particles and atomic nuclei that zip and zap through space, coming from ordinary stars, supernovae explosions, neutron stars, black holes and who knows what—the last category naturally being of greatest interest and the main impetus for a brand-new instrument. Dark matter is one of those possible mystery sources. Clumps of the stuff out in space might occasionally release blazes of particles that would set the detectors alight. Some physicists also speculate that our planet might be peppered with the odd antistar coming from distant galaxies made not of matter but of its evil antitwin.

The spectrometer's claim to fame is that it can tell the ordinary from the extraordinary, which otherwise are easily conflated. No other instrument has the combination of detectors that can tease out all the properties of a particle: mass, velocity, type, electric charge. Its closest predecessor is the PAMELA instrument, launched by a European consortium in 2006. PAMELA has seen hints of dark matter and other exotica, but its findings remain ambiguous because it lacks the ability to distinguish a low-mass antiparticle, such as a positron, from a high-mass ordinary particle with the same electric charge, such as a proton.

The AMS instrument is a monster by the standards of the space program, with a mass of seven metric tons (more than 14 times heavier than PAMELA) and a power consumption of 2,400 watts. In a strange symbiotic way, it and the space station have come to justify each other's existence. The station satisfies the instrument's thirst for power and orbital reboosts; the spectrometer, although it could never fully placate the station's many skeptics, at least means the outpost will do world-class research. As CERN's Large Hadron Collider plumbs the depths of nature on the ground, the Alpha Magnetic Spectrometer will do the same from orbit.

### SCIENTIFIC AMERICAN ONLINE

For more information on how the Alpha Magnetic Spectrometer works, visit [ScientificAmerican.com/may2011/ams](http://ScientificAmerican.com/may2011/ams)

### Time of Flight System 1

**PURPOSE:** Measure particle velocity and charge.  
**DESIGN:** Sheets of transparent polymer that glow when a charged particle passes through.  
**OPERATION:** A pair of these detectors times how fast the particle takes to cover the length of the instrument.

### Magnet

**PURPOSE:** Bend paths of charged particles.  
**DESIGN:** Permanent magnet with a field strength of 0.95 tesla. This magnet replaces the cryogenic superconducting magnet used in the original design, giving the instrument a longer lifetime.  
**OPERATION:** When passing through, a positively charged particle is deflected to the left, a negatively charged one to the right.

### Silicon Tracker

**PURPOSE:** Measure particle charge and momentum.  
**DESIGN:** Nine planes of particle detectors.  
**OPERATION:** The detectors trace out the path of each particle through the magnetic field.

### Transition Radiation Detector

**PURPOSE:** Distinguish low-mass from high-mass particles.  
**DESIGN:** 20 stacked layers of fleece and straw tubes.  
**OPERATION:** As a low-mass particle passes through the fibers in the fleece, it can emit an x-ray, which is detected by a row of gas-filled tubes underneath.

Negatively Charged Particles

Positively Charged Particles

### Anticoincidence Counter

**PURPOSE:** Identify particles that enter from the side.  
**DESIGN:** Cylinder of transparent polymer tiles that glow when a charged particle passes through.  
**OPERATION:** A particle needs to fly the length of the instrument for all the detectors to gather the necessary data. This detector registers particles that enter from the side so that the control system can discard the signal they left in other instruments.

### Time of Flight System 2

### Ring Imaging Cherenkov Detector

**PURPOSE:** Measure particle velocity.  
**DESIGN:** Aerogel and sodium fluoride ringed by light sensors.  
**OPERATION:** The speed of light in aerogel is 5 percent slower than in the vacuum; in sodium fluoride, 23 percent slower. A particle moving nearly at the vacuum speed of the light will emit a distinctive bluish cone of light known as Cherenkov radiation.

### Electromagnetic Calorimeter

**PURPOSE:** Measure particle type and direction.  
**DESIGN:** Layers of lead foil epoxied together with embedded fiber optics.  
**OPERATION:** The particle slams into the material and produces a spray of debris; the nature of the debris identifies the particle. Unlike other instruments, the calorimeter also registers uncharged particles such as photons.

# Overview

- Short introduction to cosmic-ray physics
- The AMS-02 detector on the International Space Station
- First result: Cosmic-ray positron fraction

# Cosmic rays: spectrum and composition

■ Direction information is scrambled by interstellar magnetic fields.

# Cosmic ray physics in a nutshell

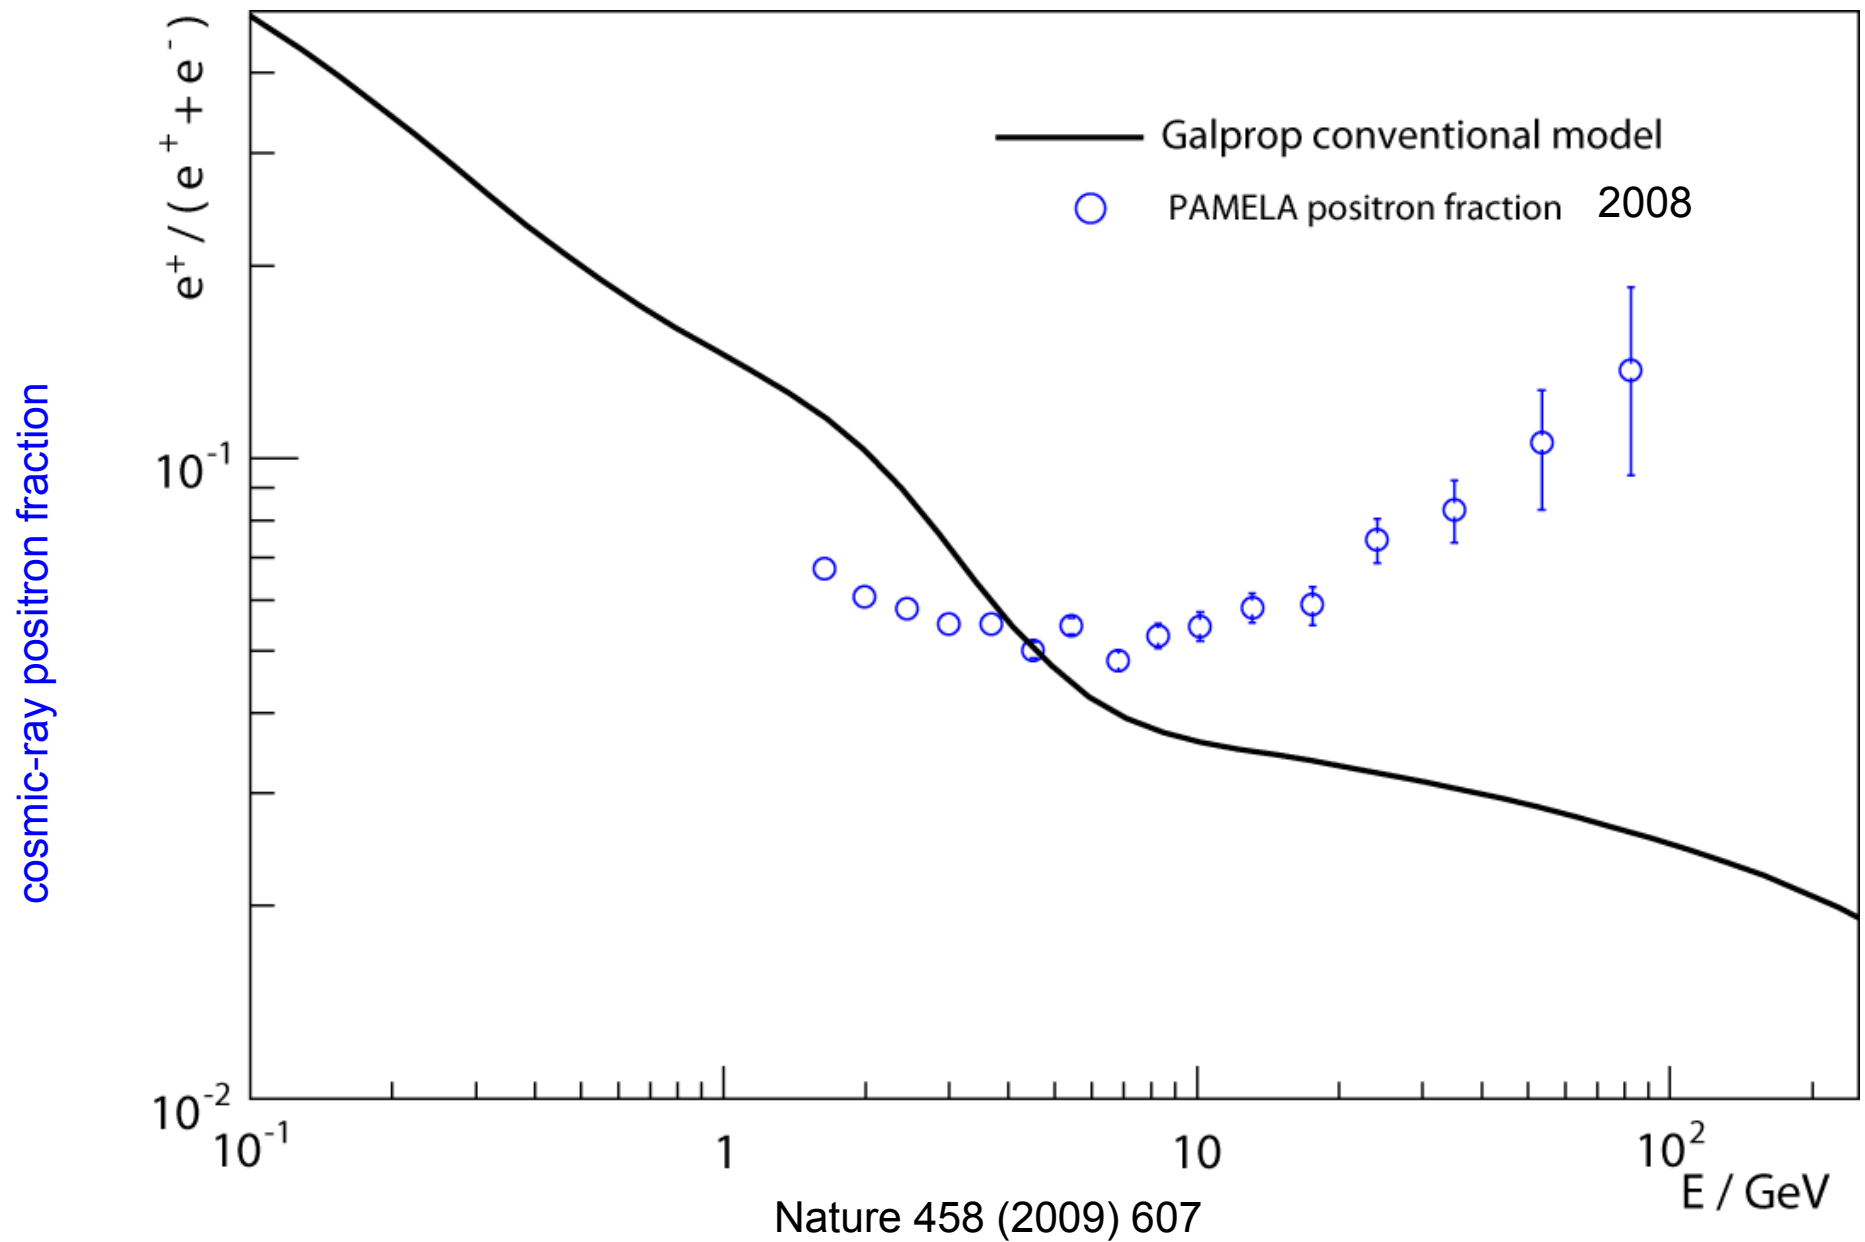

Image: GALEX, JPL-Caltech, NASA;  
Drawing: APS/Alan Stonebraker

# Positron fraction: Exotic sources of cosmic rays?

# Context: Indirect search for dark matter

M. Cirelli, arXiv: 1202.1454

Example fits: 3 TeV DM particle annihilating to  $\tau^+\tau^-$ , with a cross section of  $2 \cdot 10^{-22} \text{ cm}^3/\text{s}$

Interpreting antimatter and electron spectra in terms of dark matter requires:

- particle mass of a few TeV
- leptophilic annihilation
- *very large annihilation cross section*

Physics example	Cosmic Ray Physics Strangelets			Dark matter		Antimatter

Cosmic rays are measured at up to 2 KHz  
and data is generated at ~7 Gbit/s,  
reduced on board to an average of ~10 Mbit/s.

# AMS-02 data taking

- For every year of AMS flight:
- 20 TB raw data
- 160 TB reconstructed event data
- Data handling non-trivial!

**Thermal variables:**  
ISS Radiator positions  
ISS attitude changes (primarily for  
visiting vehicles)

**Visiting Vehicles

- TR yield proportional to  $\gamma = E/m$

1 / 20 TRD layers, AMS flight data:

# TRD proton rejection vs rigidity

# ECAL: energy resolution and proton rejection power

# 1.03 TeV electron

## First result from AMS-02: Cosmic-ray positron fraction

“First Result from the AMS on  
the ISS: Precision  
Measurement of the Positron  
Fraction in Primary Cosmic  
Rays of 0.5-350 GeV”

6.8 million positrons and  
electrons in final data sample

Selected for a  
Viewpoint in Physics and  
an Editors' Suggestion  
[Aguilar, M. et al  
(AMS Collaboration)  
Phys. Rev. Lett. 110,  
141102 (2013)]

## Example of positron selection

## AMS-02 positron fraction

- Steady increase from 10 to ~250 GeV
- No structure in the spectrum

## Comparison to earlier measurements

## A simple model

$$\Phi_{e^+} = C_{e^+} E^{-\gamma_{e^+}} + C_s E^{-\gamma_s} e^{-E/E_s}$$

$$\Phi_{e^-} = C_{e^-} E^{-\gamma_{e^-}} + C_s E^{-\gamma_s} e^{-E/E_s}$$

## Limit on dipole anisotropy

- Data are consistent with isotropic distribution of arrival directions:

$$\frac{r_e(b, l)}{\langle r_e \rangle} - 1 = \sum_{\ell=0}^{\infty} \sum_{m=-\ell}^{\ell} a_{\ell m} Y_{\ell m}(\pi/2 - b, l)$$

$$C_{\ell} = \frac{1}{2\ell + 1} \sum_{m=-\ell}^{\ell} |a_{\ell m}|^2.$$

$$\delta = 3\sqrt{C_1/4\pi}$$

AMS-02:

$\delta < 0.036$  at the 95% confidence level.

- Dark matter annihilating directly to  $e^+ e^-$  or  $\mu^+ \mu^-$  no longer capable of describing observed rise in positron fraction.
- Annihilation via light intermediate states into muons and pions consistent with data, for DM masses of 1.5 – 3 TeV,  $\langle\sigma v\rangle$  as high as  $(6 - 23) \times 10^{-24} \text{ cm}^3/\text{s}$
- Describing the Fermi all-electron spectrum at the same time requires spectral break in cosmic-ray electrons. (May be expected if single or few local sources dominate.)

# Dark matter in the light of AMS-02 results

Bergström et al., PRL  
111 (2013) 171101

- Take generic model from AMS paper as background curve
- Try to fit lepton spectra from annihilating dark matter to AMS positron fraction

# Dark matter in the light of AMS-02 results

Bergström et al., PRL  
111 (2013) 171101

- Take generic model from AMS paper as background curve
- Try to fit lepton spectra from annihilating dark matter to AMS positron fraction

# Astrophysical sources for positrons

Positrons inevitably produced in magnetosphere of pulsars and accelerated in pulsar wind nebula.

# Pulsar models also still work!

Cholis and Hooper,  
PRD 88 (2013) 023013

- Sum of known pulsars, assuming
  - exponentially cutoff power law spectra
  - 10-20% of spin-down power converted to CR acceleration
  - break in CR electron spectrum as before (spectral hardening at 100 GeV)

## ■ More ideas:

- Supernova remnants (radioactive nuclei from supernova ejecta) as positron sources (Erlykin & Wolfendale)
- Acceleration of secondary  $e^\pm$  produced through pp interactions inside the primary sources (Ahlers et al.)
- Propagation effects (Blum et al.)

ICRC 2013:  
Preliminary results on cosmic-ray fluxes

# AMS-02 electron and positron spectra

# Summary

- Cosmic-ray research aims at answering fundamental questions about our Universe.
- AMS-02 will be the leading instrument in its field for many years to come.
- Data analysis is an extremely complex endeavour:
  - challenging environment in space
  - interplay of different sub-detectors
  - enormous data volume
- AMS-02 has measured cosmic-ray positron fraction with exquisite precision:
  - Steady increase from 10 to ~250 GeV
  - No structure in the spectrum
- Results have profound impact on the modelling of CR sources: dark matter or pulsar wind nebulae or something else (SNRs?) ?
- Measurement of anisotropy in positron fraction extremely important in this context.
- First results on major particle fluxes shown at ICRC 2013 in July.
- Coming soon:
  - update on positron fraction,
  - $e^+$  and  $e^-$  fluxes,
  - proton and helium fluxes

# The Cosmos is the Ultimate Laboratory.

Cosmic rays can be observed at energies higher than any accelerator.
