Fig. 3. Dependence of the mass-59 e^- -capture GCR relative abundances at Earth on the time delay between nucleosynthesis and acceleration. Different curves assume different fractions f_0 of mass-59 nuclei synthesized as ^{59}Ni at the source. The W&W values of f_0 come from the SN II yield calculations of Woosley and Weaver (1995). CRIS abundances are shown as a hatched region.

Fig. 4. Mean free paths for electron attachment and stripping (Crawford, 1979) of GCR Co in the ISM as a function of energy, assuming an ISM composition of 90% H, 10% He. Also shown is the mean free path for GCR fragmentation in the ISM (Tripathi et al., 1999). The hatched region indicates the approximate energy range for the GCR Co observed by CRIS, with a mean ISM energy of ~ 500 MeV/nuc.

Mixed EC/ β -decay isotopes

- Stellar conditions: EC hindered, weak β^+/β^- decay channel determines $t_{1/2}$
- 10^7 pps injected, 30min measured \Rightarrow ~ 1 event/d if partial $t_{1/2} = 25000$ y

^{54}Mn

- CR chronometer if partial $t_{1/2}$ of β^- branch known
- β^+ branch measured
- **Assuming same log ft for β^- branch** (factor 2-3 uncertainty)
- Direct: $\beta^- < 3.9 \cdot 10^{-5} \Rightarrow t_{1/2}(\beta^-) > 22000 \text{ y}$
- Shell model prediction: $t_{1/2}(\beta^-) \sim 500\,000 \text{ y}$
Martinez-Pinedo et al., PRL 81, 281 (1998)
- Form factor for β^- larger than for β^+ decay
 \Rightarrow Quenching of GT necessary, not necessary for forbidden transitions

	β^+ branch		partial half-life (β^+) (years)		est. β^- branch	est. part. half-life (β^-) (years)
Sur (1989)	$<4.4\text{E-}08$		$>2.0\text{E+}07$			>40000
da Cruz (1993)	$<5.7\text{E-}09$		$>1.5\text{E+}08$		$<2.9\text{E-}06$	>295000
Wuosmaa (1997)	$1.2\text{E-}09$	$\pm 0.3\text{E-}09$	$7.10\text{E+}08$	$\pm 1.5\text{E+}08$	$\sim 6.0\text{E-}07$	~ 630000
Zaerpoor (1999)	$1.8\text{E-}09$	$\pm 0.8\text{E-}09$	$4.70\text{E+}08$	$\pm 2.1\text{E+}08$	$\sim 9.0\text{E-}07$	~ 930000

^{56}Ni decay

- Most abundant isotope from SN explosions: early SN lightcurve
- Measure for acceleration time scale if $t_{1/2} > 10 \text{ My}$
- Measurement (0.1 MBq source, $8 \cdot 10^{10}$ at.):
 $\beta^+(158 \text{ keV}) < 6.3 \cdot 10^{-5} \% \Rightarrow t_{1/2}(\beta^+) > 27000 \text{ y}$
Zaerpoor et al., PRC 59, 3393 (1999)

- Shell model predictions Lund Fisker et al., EPJA 5, 229 (1999)

Partial $t_{1/2}(\beta^+)$

2+: $(0.6-3.3) \cdot 10^8 \text{ y}$

3+: $(3.7-4.2) \cdot 10^4 \text{ y} \Rightarrow$ **No CR chronometer**

4+: $(2.6-5.0) \cdot 10^{12} \text{ y}$

- Quenching of GT, not for forbidden transition
- If quenched: $t_{1/2}(\beta^+) = 73000 \text{ y}$

Mixed EC/ β -decay isotopes: s process

- s-process "branchings"
- Determines how much material is transferred to next isotope
- Interior of stars: high recombination rates but also high temperatures
- $T \approx 30\text{-}1000$ MK

43.9% EC/17.6% β^+

6.1% EC/ 2.2% β^+

β -delayed neutron emission probability

$$S_n < Q_\beta$$

Important nuclear structure information
 P_n : β -strength above S_n
 $t_{1/2}(^AZ+1)$: sensitive to low-lying β -strength

- Important for nuclear structure, astrophysics (r-process), and reactor physics
- ^8He - ^{150}La : ~ 200 datasets available, ~ 75 in non-fission region ($A < 70$)

"Biased" Conclusion

Physics Case:

New long-lived isomeric states
Lifetimes of exotic nuclei
Beta-decay of heavy-Z HCI
Beta-decay of low-, medium-Z HCI
Beta-decay n-emission
"GSI Oscillations"
7Be and other light-Z isotopes
Isomeric beams, NEEC

Comments:

Single-particle sensitivity → high energy
Single-particle sensitivity → high energy
Highest atomic charge states → high energy, Super-EBIT
High intensities of stored beams → TSR
If T1/2 allows → TSR since no long cooling is needed
Single-particle sensitivity → high energy, but TSR is possible
Few-electron systems → TSR is unique
Fast slowing down → CRYRING is better

All lifetime studies can run already at 3.8 MeV/u

Paul Kienle
1931-2013

Transverse Schottky pick-up - Test of the V-A nature of weak interaction

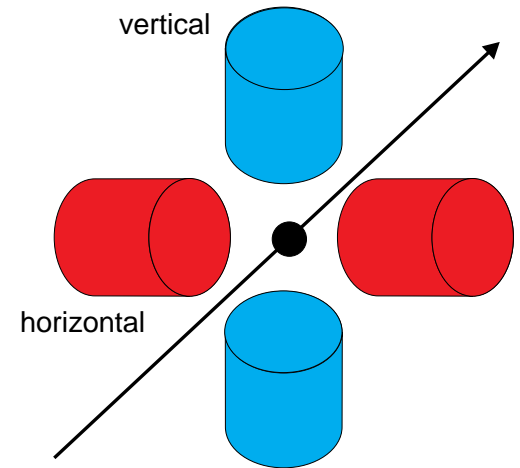

Fermi transitions

Gamow-Teller transitions

Transverse Schottky

accurate determination of transversal component (vertical and horizontal) of the momentum transfer to a recoiling ion in a decay or reaction

Both Schottky detectors together will enable fully-kinematical studies of decays and/or reactions (e.g. to test the fundamental nature of weak interaction via an accurate measurement of the the shape of a beta-decay spectrum)

Physics at Storage Rings

Single-particle sensitivity

High atomic charge states

Long storage times

Broad-band measurements

High resolving power

Very short lifetimes

Direct mass measurements of exotic nuclei

Radioactive decay of highly-charged ions

Charge radii measurements [DR, scattering]

Experiments with polarized beams

Experiments with isomeric beams [DR, reactions]

Nuclear magnetic moments [DR]

Astrophysical reactions [(p,g), (a,g) ...]

In-ring nuclear reactions

Revolution-frequency difference δf of the recoils just after decay: $\delta f = f_{\text{dec}} - f_{\text{cool}}$

For a (longitudinally) unpolarized beam the distribution should have a rectangular shape

For a (steadily controlled) polarized beam the distribution would provide the helicity of the neutrino

From v_r and m_r one gets the momentum of the (monochromatic) neutrino: $(pc)_d = m_d cv_d = (pc)_v$

From m_p and m_d one gets its energy: $E_v = (m_p - m_d) c^2$
and then $\beta_v = E_v / (pc)_v$

245 MHz Resonator: bei $\omega = 0,907/s$ $a = 0,03(3)$, **no** significant modulations

Advantages & Drawbacks

- + Independent on worldwide ^3He shortage
- + Decay detector: cheaper than neutron detector array
- + Only few atoms/ injection needed
- + Independent on neutron energy (detection efficiency problem)

- No cooling possible (isotopes too short-lived)
- Low efficiency (could be increased by 2nd detector)
- Produced ions have to be transferred from FRS into ESR (losses)

Possible cases: β_n standards

Possible standards selected by IAEA consultants' meeting (2011)

^9Li : $P_n = 50.8$ (2) %

^{17}N : $P_n = 95.1$ (7) %

^{87}Br : $P_n = 2.43$ (14) %

^{88}Br : $P_n = 6.67$ (17) %

^{94}Rb : $P_n = 10.19$ (30) %

^{95}Rb : $P_n = 8.89$ (33) %

^{137}I : $P_n = 7.33$ (38) %

- Should be measured with independent methods and agree
- Standard for every mass region
- Missing: $A > 150$ and $A \sim 60$

β -delayed neutron emitters

- Measuring P_n values without neutron detectors
- Complementary to standard methods

Available methods (up to now):

- “ n/β ”: Neutron-beta coincidences
- “ $n-\beta$ ”: Neutrons and betas counted separately (no coincidences) but simultaneously
- “ γ^{AZ+n} ”: Abundance of precursor determined via gamma-counting of any β -decay daughter
- “ P_n^{AZ} ”: Normalization of the ratio $\varepsilon_b/\varepsilon_n$ with known P_n value from precursor AZ
- “ $\gamma-\gamma$ ”: Number of neutron decays determined only via γ -counting
- “**ion**”: Ion counting
- “**fiss**”: Fission yields
