

The inflaton as a dark matter candidate

Thursday 29 May 2014 15:50 (20 minutes)

We propose a novel mechanism for the incomplete decay of the inflaton field that, while reheating the universe after inflation, leaves a stable oscillating scalar condensate that can account for the observed dark matter abundance. We discuss possible embeddings of this mechanism within different inflationary models, in particular chaotic and hybrid inflation, as well as within extensions of the Standard Model of particle physics.
