Introduction

Part 1: Passage of particles through matter

- Charges particles, Photons, Neutrons, Neutrinos
- Momentum measurements, Combining measurements.

Part 2: Particle Detection

- Ionisation detector
- Scintillation detectors
- Semiconductor detectors

Experimental Particle Physics

Accelerators

- Luminosity, energy, quantum numbers

Detectors

- Efficiency, speed, granularity, resolution

Trigger/DAQ

- Efficiency, compression, through-put, physics models

Offline analysis

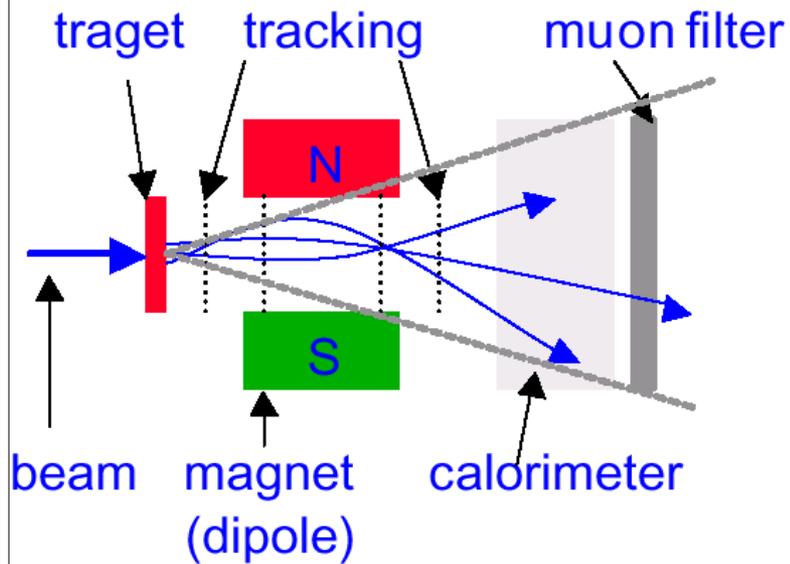

- Signal and background, physics models.

The primary factors for a successful experiment are the accelerator and detector/trigger system, and losses there are not recoverable.

Geometrical concepts

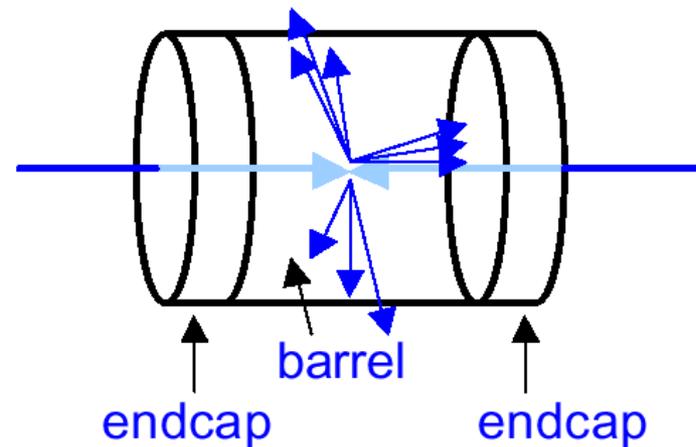

Fix target geometry

Structure within the Atom

If the protons and neutrons in this picture were 10 cm across, then the quarks and electrons would be less than 0.1 mm in size and the entire atom would be about 10 km across.

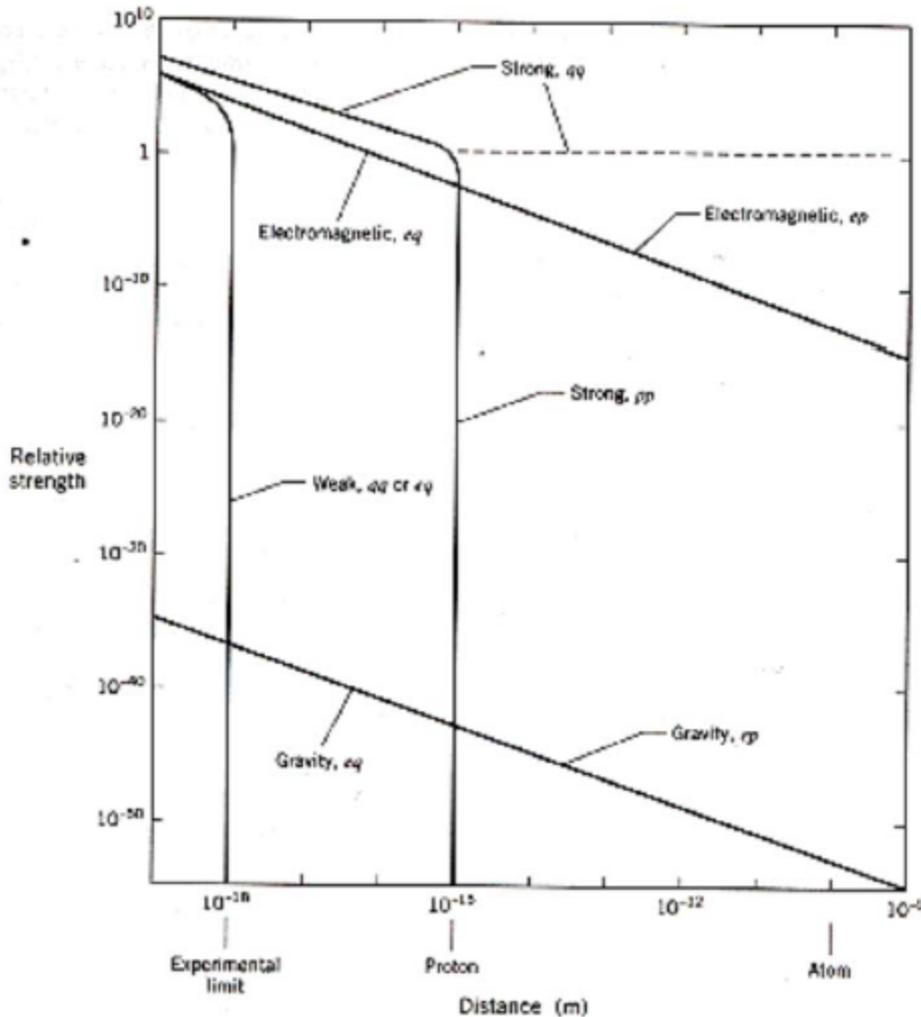

Concentrate on electromagnetic forces since a combination of their strength and reach make them the primary responsible for energy loss in matter.

For neutrons, hadrons generally and neutrinos other effects obviously enter.

PROPERTIES OF THE

Property \ Interaction	Gravitational	Weak (Electroweak)		Electromagnetic	Strong		
					Fundamental	Residual	
Acts on:	Mass – Energy	Flavor		Electric Charge	Color Charge	See Residual Strong Interaction Note	
Particles experiencing:	All	Quarks, Leptons		Electrically charged	Quarks, Gluons	Hadrons	
Particles mediating:	Graviton (not yet observed)	W^+	W^-	Z^0	γ	Gluons	Mesons
Strength relative to electromag for two u quarks at:	10^{-41}	0.8		1	25	Not applicable to quarks	
for two protons in nucleus	10^{-41}	10^{-4}		1	60		
	10^{-36}	10^{-7}		1	Not applicable to hadrons	20	

Strength versus distance

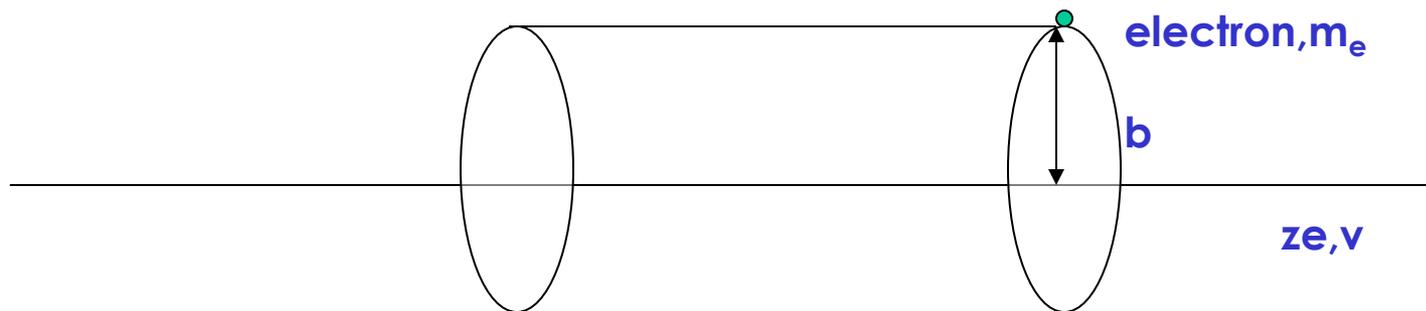

- At atomic distances only EM & gravity have sizable strengths
- EM is ~40 orders of magnitude stronger than gravity
- If quarks could be separated force would be enormous (see dashed line)
- At proton size distances strong force turns on & becomes ~100 times stronger than EM force
- At distances ~1/1000 of proton size weak force turns on abruptly

Heavy charged particles

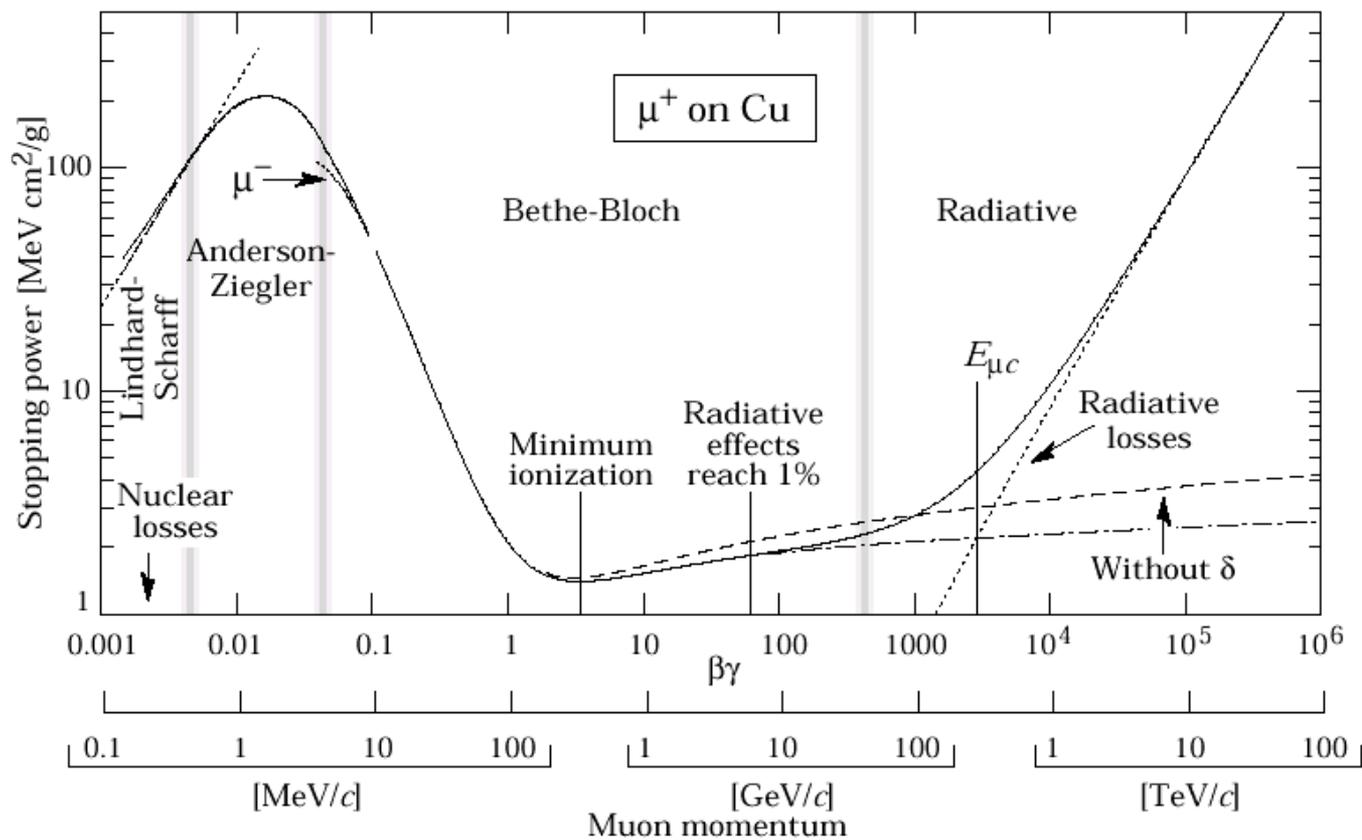

Heavy charged particles transfer energy mostly to the atomic electrons, ionising them. We will later come back to not so heavy particles, in particular electrons/positrons.

Usually the Bethe Bloch formula is used to describe this - and most of features of the Bethe Bloch formula can be understood from a very simple model :

- 1) Let us look at energy transfer to a single electron from heavy charged particle passing at a distance b
- 2) Let us multiply with the number of electrons passed
- 3) Let us integrate over all reasonable distances b

Heavy charges particles

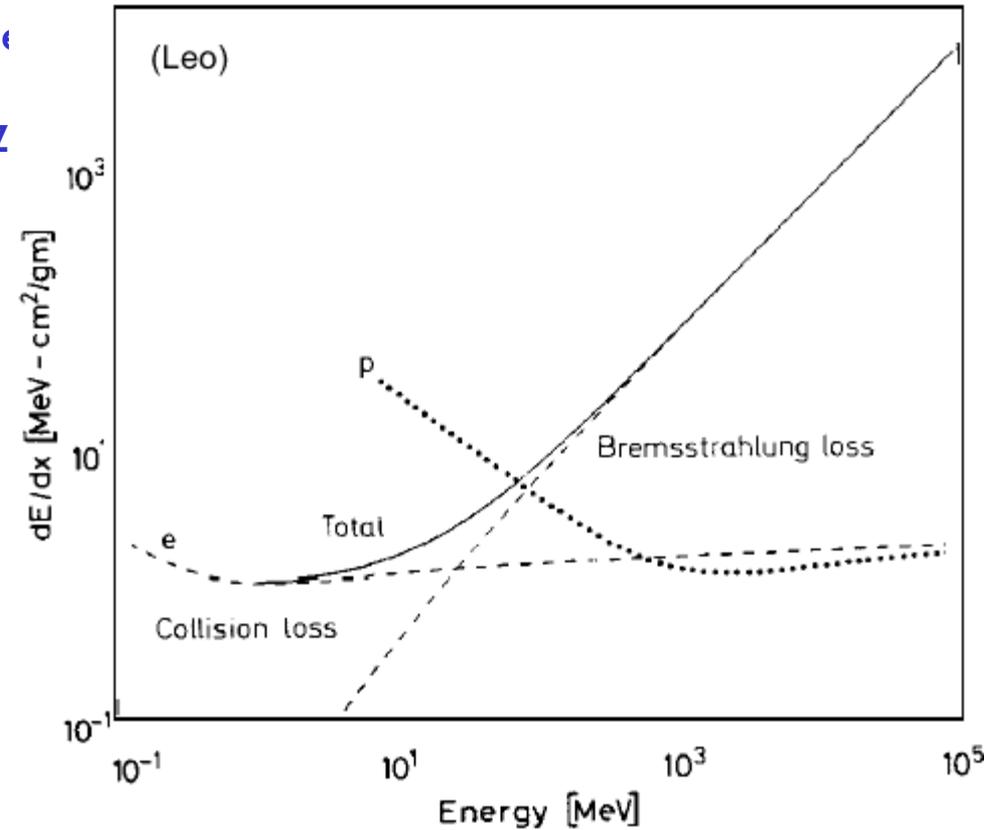

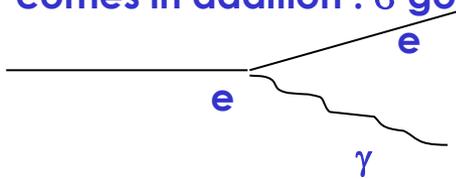

$$\left\langle \frac{dE}{dx} \right\rangle = -4\pi N_A r_e^2 m_e c^2 z^2 \frac{Z}{A} \frac{1}{\beta^2} \left[\frac{1}{2} \ln \frac{2m_e c^2 \gamma^2 \beta^2}{I^2} T^{\max} - \beta^2 - \frac{\delta}{2} \right]$$

Electrons and Positrons

Electrons/positrons; modify Bethe Bloch to take into account that incoming particle has same mass as the atomic electrons

Bremsstrahlung in the electrical field of a charge Z comes in addition : σ goes as $1/m^2$

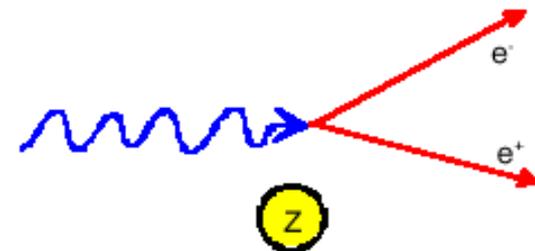

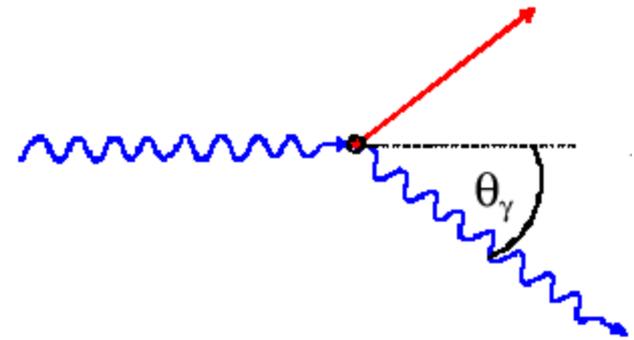

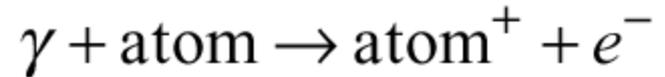

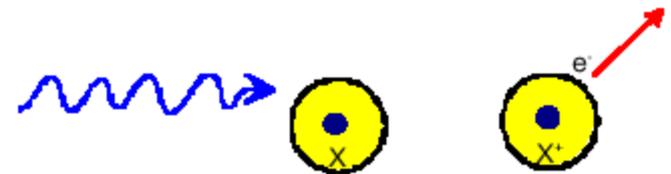

Three processes :

Photoelectric effect (Z^5); absorption of a photon by an atom ejecting an electron. The cross-section shows the typical shell structures in an atom.

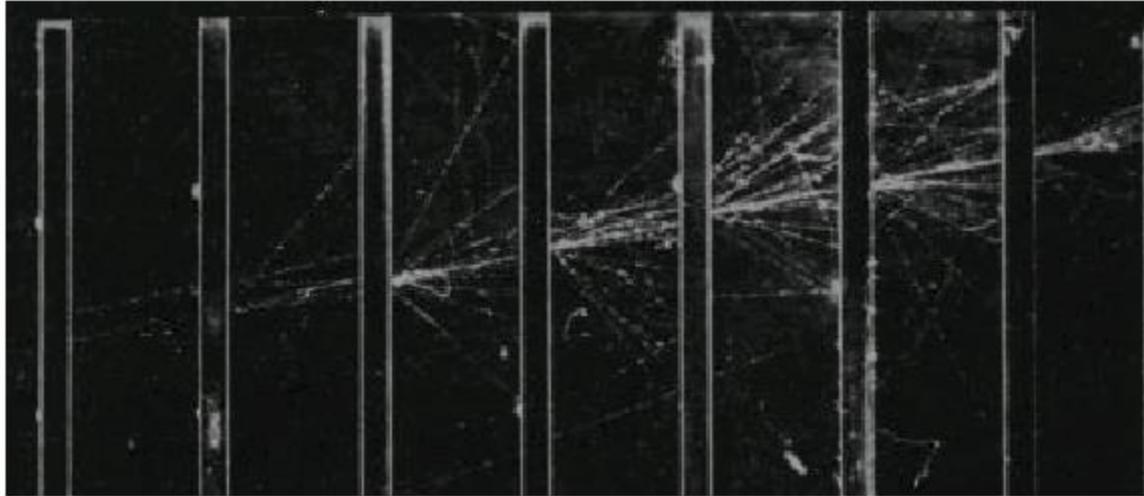

Compton scattering (Z); scattering of a photon again a free electron (Klein Nishina formula). This process has well defined kinematic constraints (giving the so called Compton Edge for the energy transfer to the electron etc) and for energies above a few MeV 90% of the energy is transferred (in most cases).

Pair-production (Z^2+Z); essentially bremsstrahlung again with the same machinery as used earlier; threshold at $2 m_e = 1.022$ MeV. Dominates at a high energy.

absorbers

From C.Joram

Considering only Bremsstrahlung and Pair Production with one splitting per radiation length (either Brems or Pair) we can extract a good model for EM showers.

Longitudinal shower development

Text from C.Joram

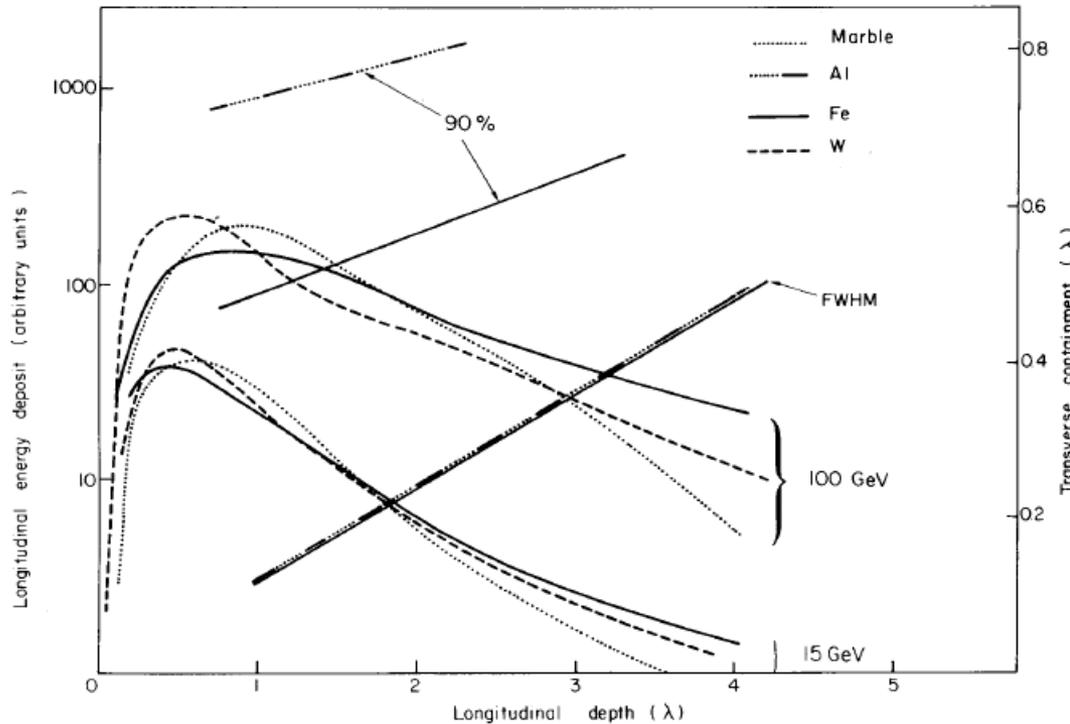

$$t_{\max}(\lambda_I) \approx 0.2 \ln E[\text{GeV}] + 0.7$$

$$t_{95\%} \approx a \ln E + b$$

For Iron: $a = 9.4$, $b = 39$

$E = 100 \text{ GeV}$

$\rightarrow t_{95\%} \approx 80 \text{ cm}$

(C. Fabjan, T. Ludlam, CERN-EP/82-37)

- **Additional strong interactions for hadrons (p,n, etc) ; hadronic absorption/interaction length and hadronic showers**

Neutrinos interact only weakly \rightarrow tiny cross-sections

For their detection we need again first a charged particle.

Possible detection reactions:

- $\nu_\ell + n \rightarrow \ell^- + p \quad \ell = e, \mu, \tau$
- $\bar{\nu}_\ell + p \rightarrow \ell^+ + n \quad \ell = e, \mu, \tau$

The cross-section for the reaction $\nu_e + n \rightarrow e^- + p$ is of the order of 10^{-43} cm² (per nucleon, $E_n \approx$ few MeV).

\rightarrow detection efficiency $\epsilon_{\text{det}} = \sigma \cdot N^{\text{surf}} = \sigma \cdot \rho \frac{N_A}{A} d$

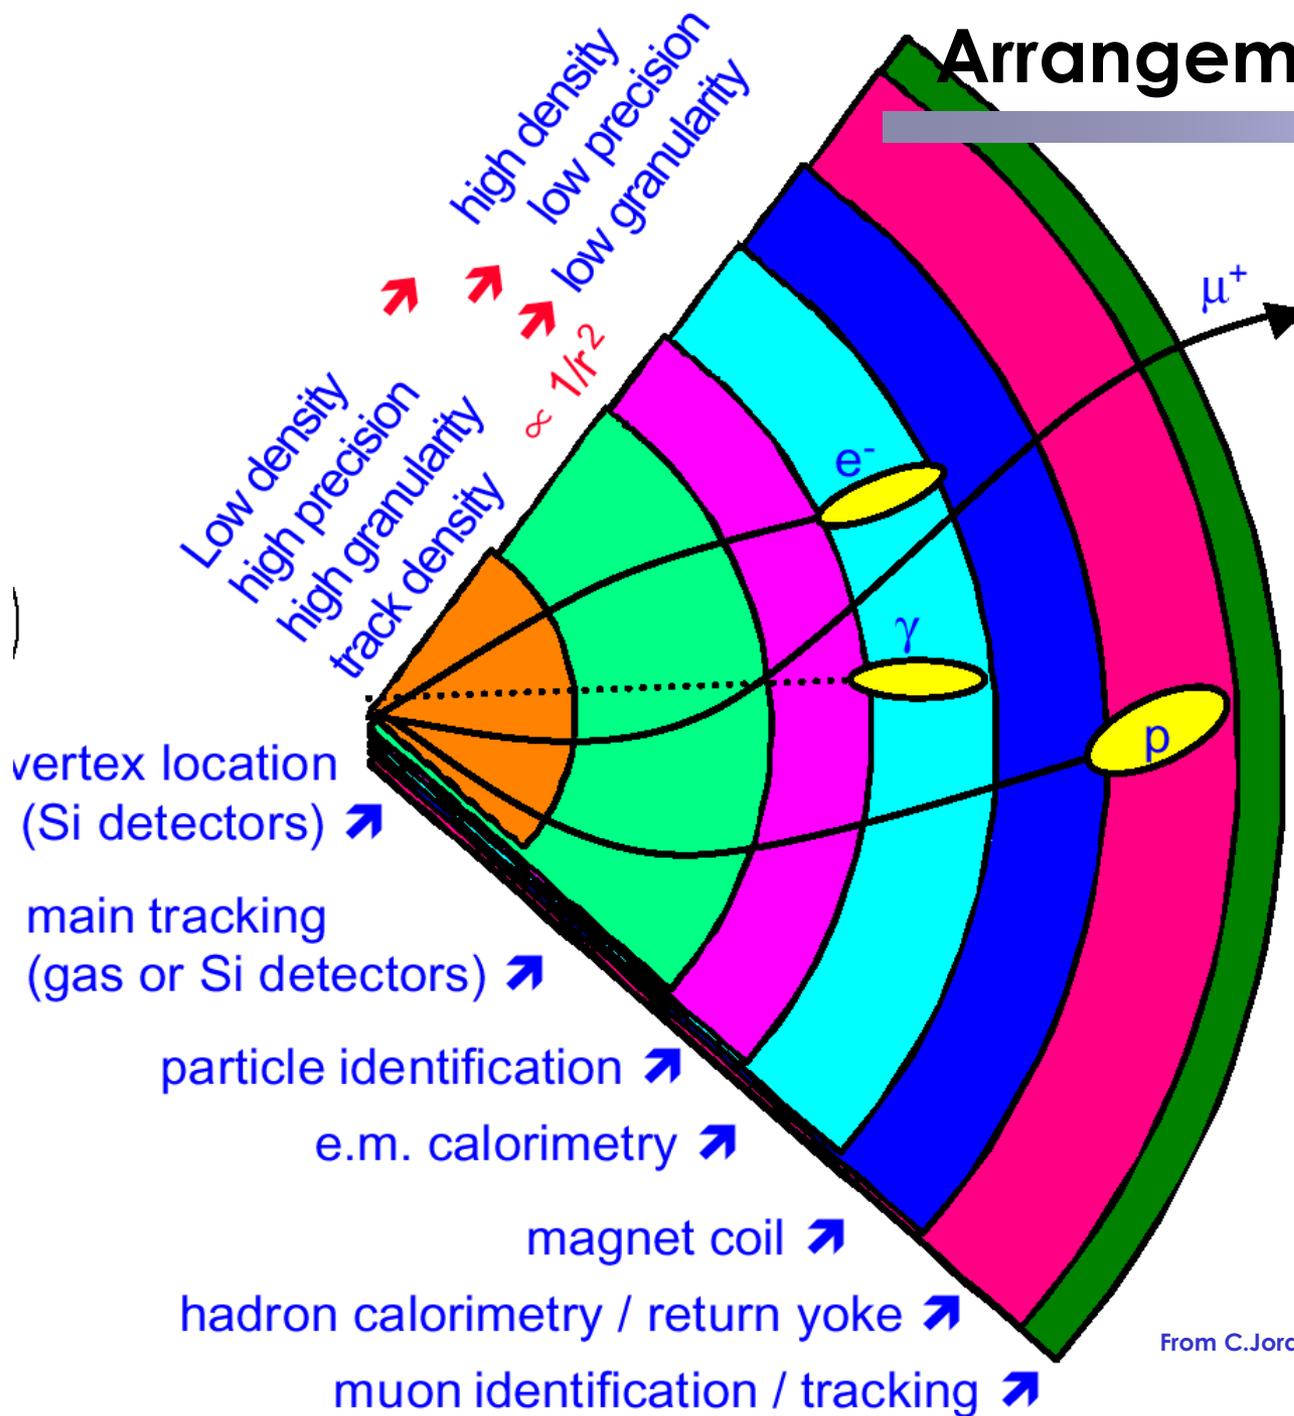

1 m Iron: $\epsilon_{\text{det}} \approx 5 \cdot 10^{-17}$

Neutrino detection requires big and massive detectors (ktons) and high neutrino fluxes.

In collider experiments fully hermetic detectors allow to detect neutrinos indirectly:

- ◆ Sum up all visible energy and momentum.
- ◆ Attribute missing energy and momentum to neutrino.

Arrangement of detectors

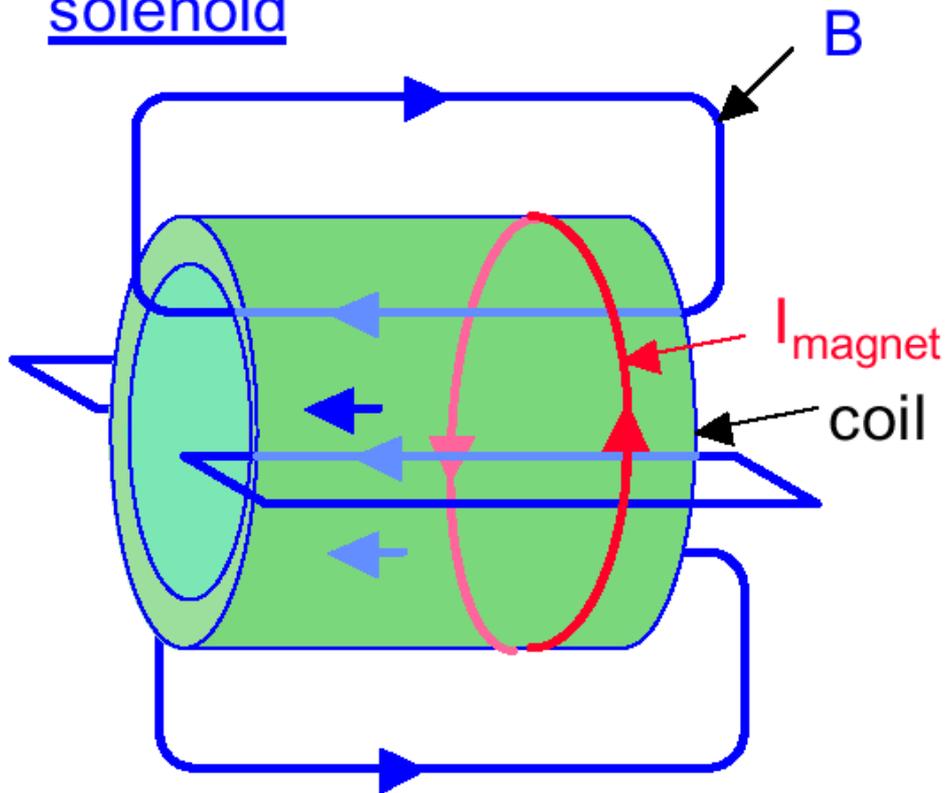

We see that various detectors and combination of information can provide particle identification; for example p versus EM energy for electrons; EM/HAD provide additional information, so does muon detectors, EM response without tracks indicate a photon; secondary vertices identify b,c, τ's; isolation cuts help to identify leptons

See the Particle Data Book for a discussion of magnets, stored energy, fields and costs.

Momentum measurement

$$p_T = qB\rho$$

$$p_T \text{ (GeV/c)} = 0.3B\rho \text{ (T} \cdot \text{m)}$$

$$\frac{L}{2\rho} = \sin\theta/2 \approx \theta/2 \rightarrow \theta \approx \frac{0.3L \cdot B}{p_T}$$

$$\Delta p_T = p_T \sin\theta \approx 0.3L \cdot B$$

$$s = \rho(1 - \cos\theta/2) \approx \rho \frac{\theta^2}{8} \approx \frac{0.3 L^2 B}{8 p_T}$$

the sagitta s is determined by 3 measurements with error $\sigma(x)$:

$$s = x_2 - \frac{x_1 + x_3}{2}$$

$$\left. \frac{\sigma(p_T)}{p_T} \right|^{meas.} = \frac{\sigma(s)}{s} = \frac{\sqrt{\frac{3}{2}}\sigma(x)}{s} = \frac{\sqrt{\frac{3}{2}}\sigma(x) \cdot 8 p_T}{0.3 \cdot BL^2}$$

for N equidistant measurements, one obtains

(R.L. Gluckstern, NIM 24 (1963) 381)

$$\left. \frac{\sigma(p_T)}{p_T} \right|^{meas.} = \frac{\sigma(x) \cdot p_T}{0.3 \cdot BL^2} \sqrt{720/(N+4)} \quad (\text{for } N \geq \approx 10)$$

ex: $p_T=1$ GeV/c, $L=1$ m, $B=1$ T, $\sigma(x)=200\mu\text{m}$, $N=10$

$$\left. \frac{\sigma(p_T)}{p_T} \right|^{meas.} \approx 0.5\% \quad (s \approx 3.75 \text{ cm})$$

Magnetic fields

Lecture set 2 : How are reactions of the various particles with detectors turned into electrical signals. We would like to extract position and energy information channel by channel from our detectors.

Three effects are usually used :

1 Ionisation

2 Scintillation

3 Semi Conductors

and these are used in either for tracking, energy measurements, photon detectors for Cherenkov or TRT, etc

and from then on it is all online (trigger, DAQ) and offline treatment and analysis

Ionisation Detectors

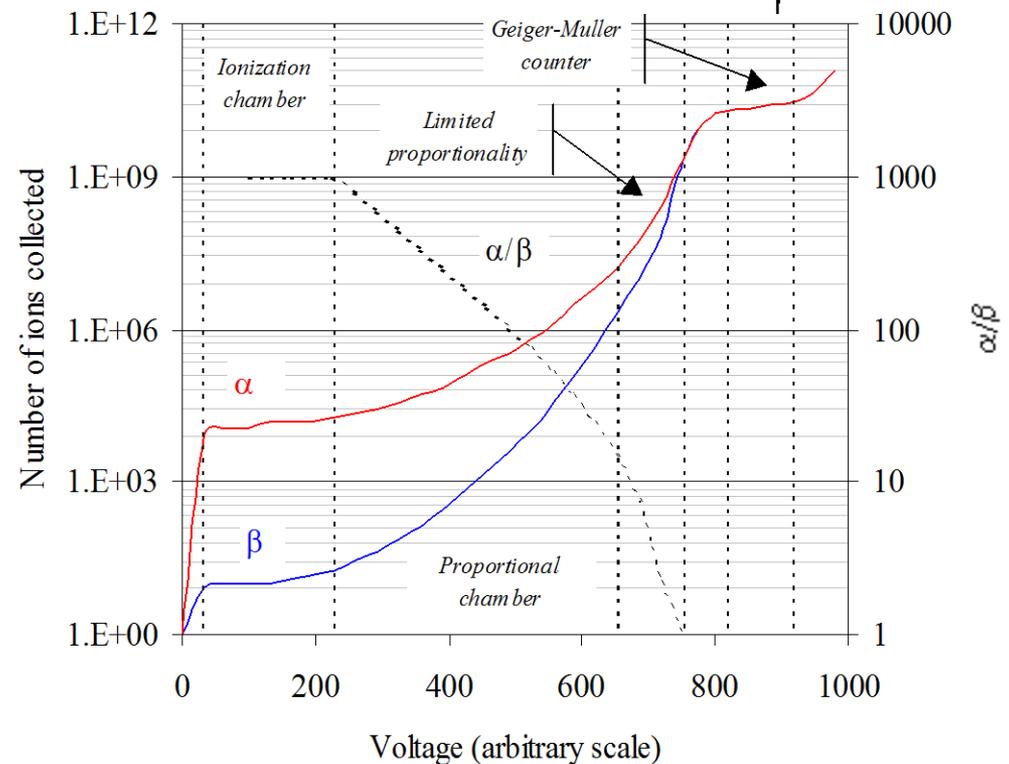

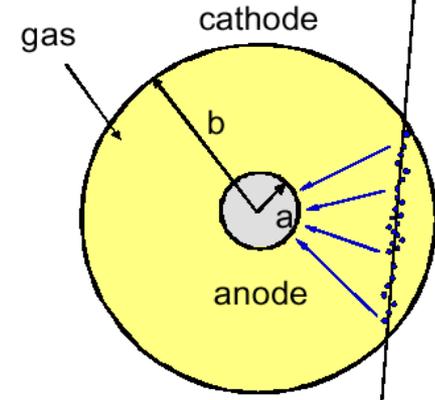

The different regions :

Recombination before collection.

Ionisation chamber; collect all primary charge.
Flat area.

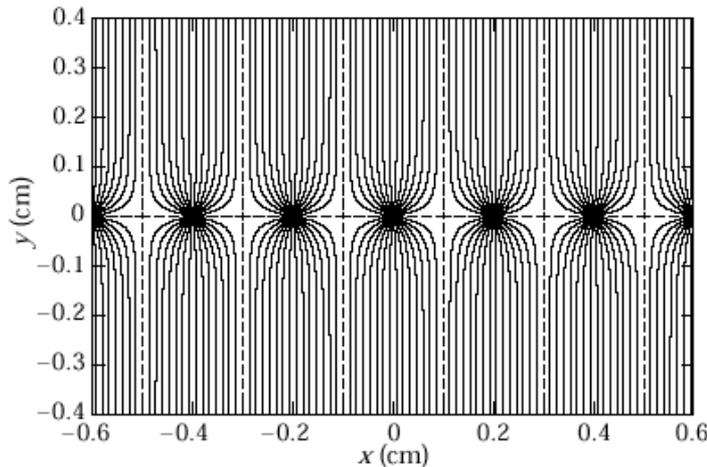

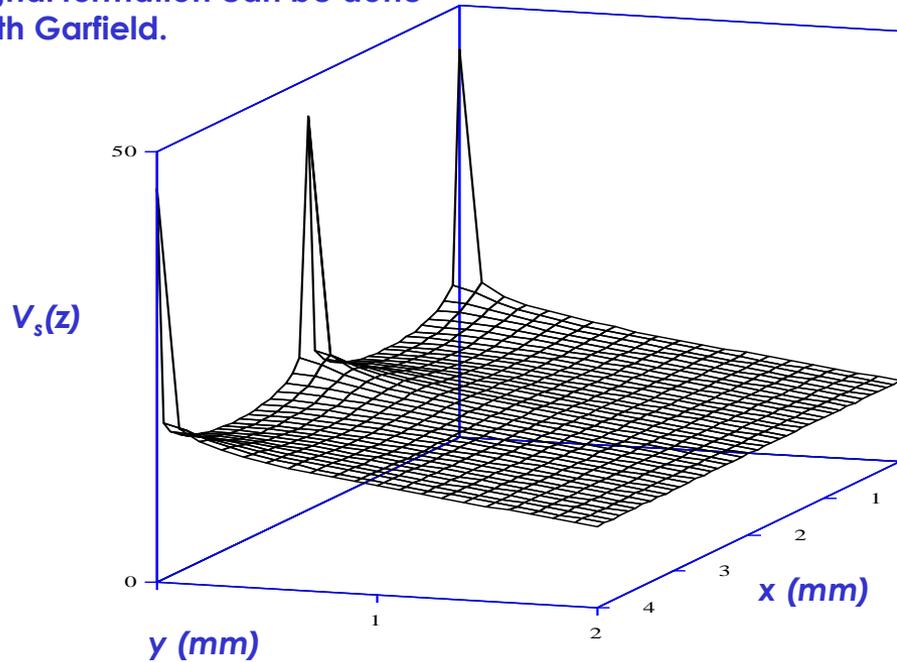

Proportional counter (gain to 10^6); secondary avalanches need to be quenched.
Limited proportionality (secondary avalanches distorts field, more quenching needed).

Geiger Muller mode, avalanches all over wire, strong photoemission, breakdown avoided by cutting HV.

Ionisation Detectors

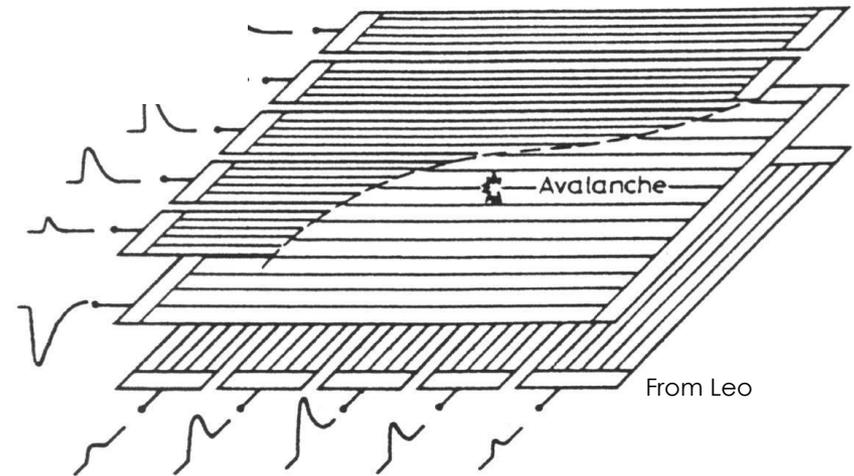

Advanced calculations of electric field, drift, diffusion and signal formation can be done with Garfield.

Two dimensional readout can be obtained by; crossed wires, charge division with resistive wires, measurement of timing differences or segmented cathode planes with analogue readout

Resolution given by (binary readout) : $\sigma = d / \sqrt{12}$

Analogue readout and charge sharing can improve this significantly when the left/right signal size provide more information about the hit position.

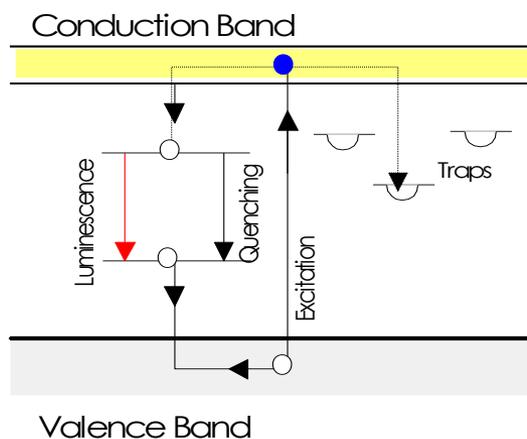

$$y = \frac{\sum (Q_i - b) y_i}{\sum (Q_i - b)}$$

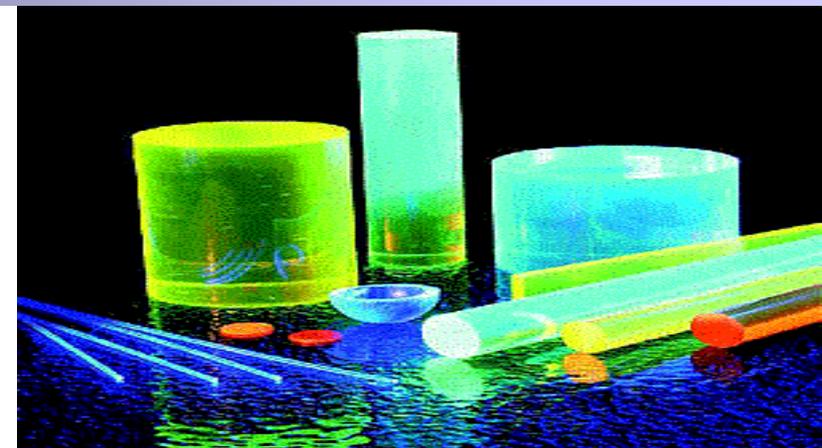

Inorganic Crystalline Scintillators

The most common inorganic scintillator is sodium iodide activated with a trace amount of thallium [NaI(Tl)],

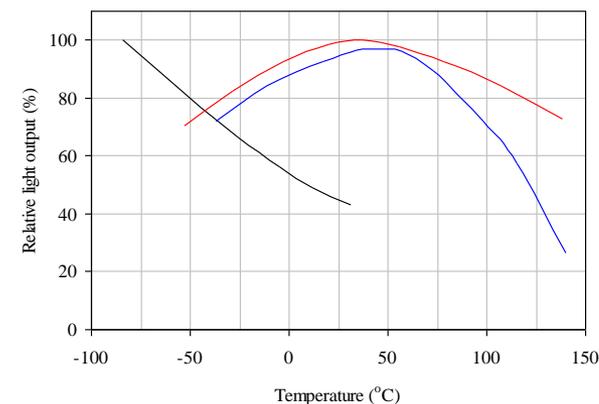

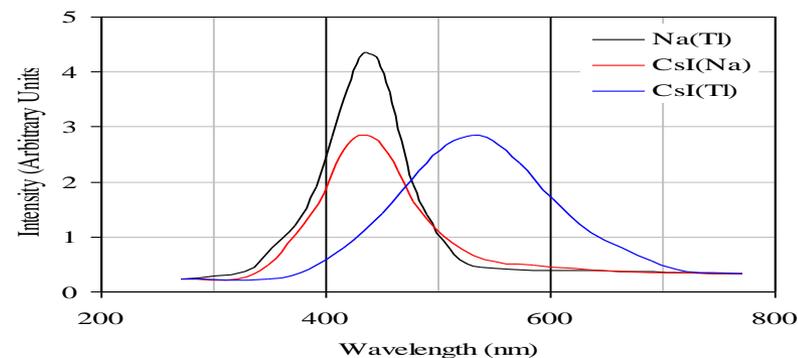

Energy bands in impurity activated crystal

Strong dependence of the light output and the decay time with temperature.

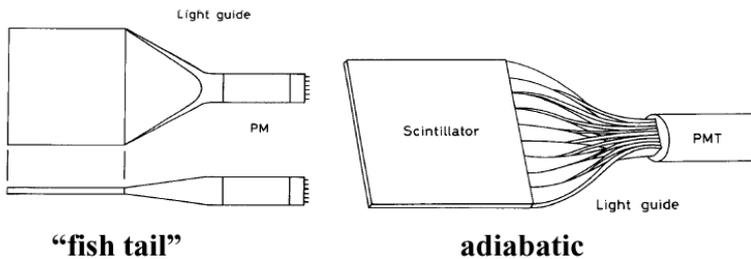

<http://www.bicron.com>.

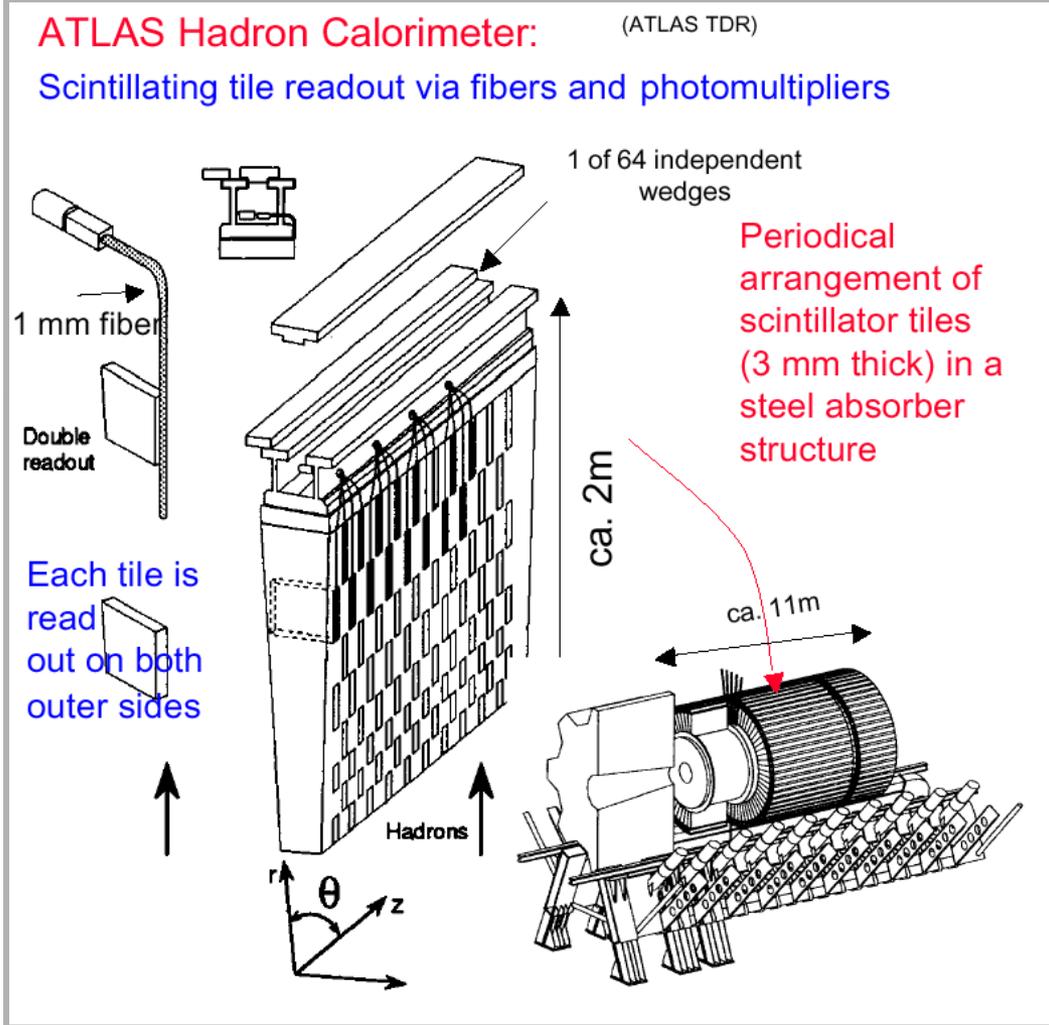

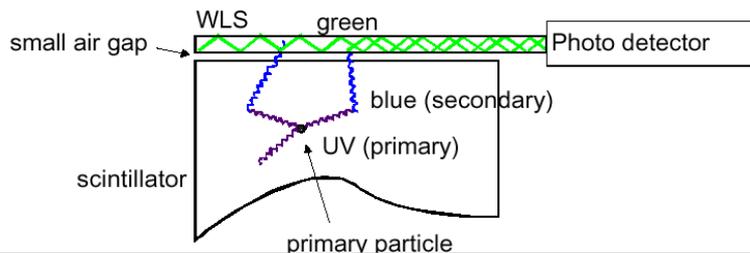

External wavelength shifters and light guides are used to aid light collection in complicated geometries; must be insensitive to ionising radiation and Cherenkov light. See examples.

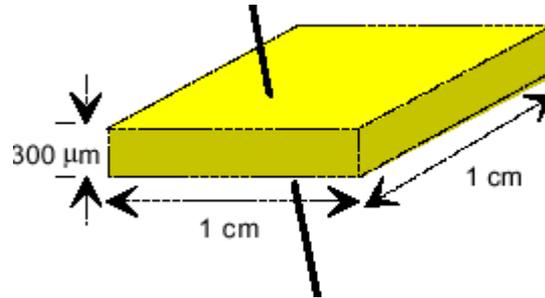

- ◆ Light guides: transfer by total internal reflection (+outer reflector)

- ◆ wavelength shifter (WLS) bars

From C.Joram

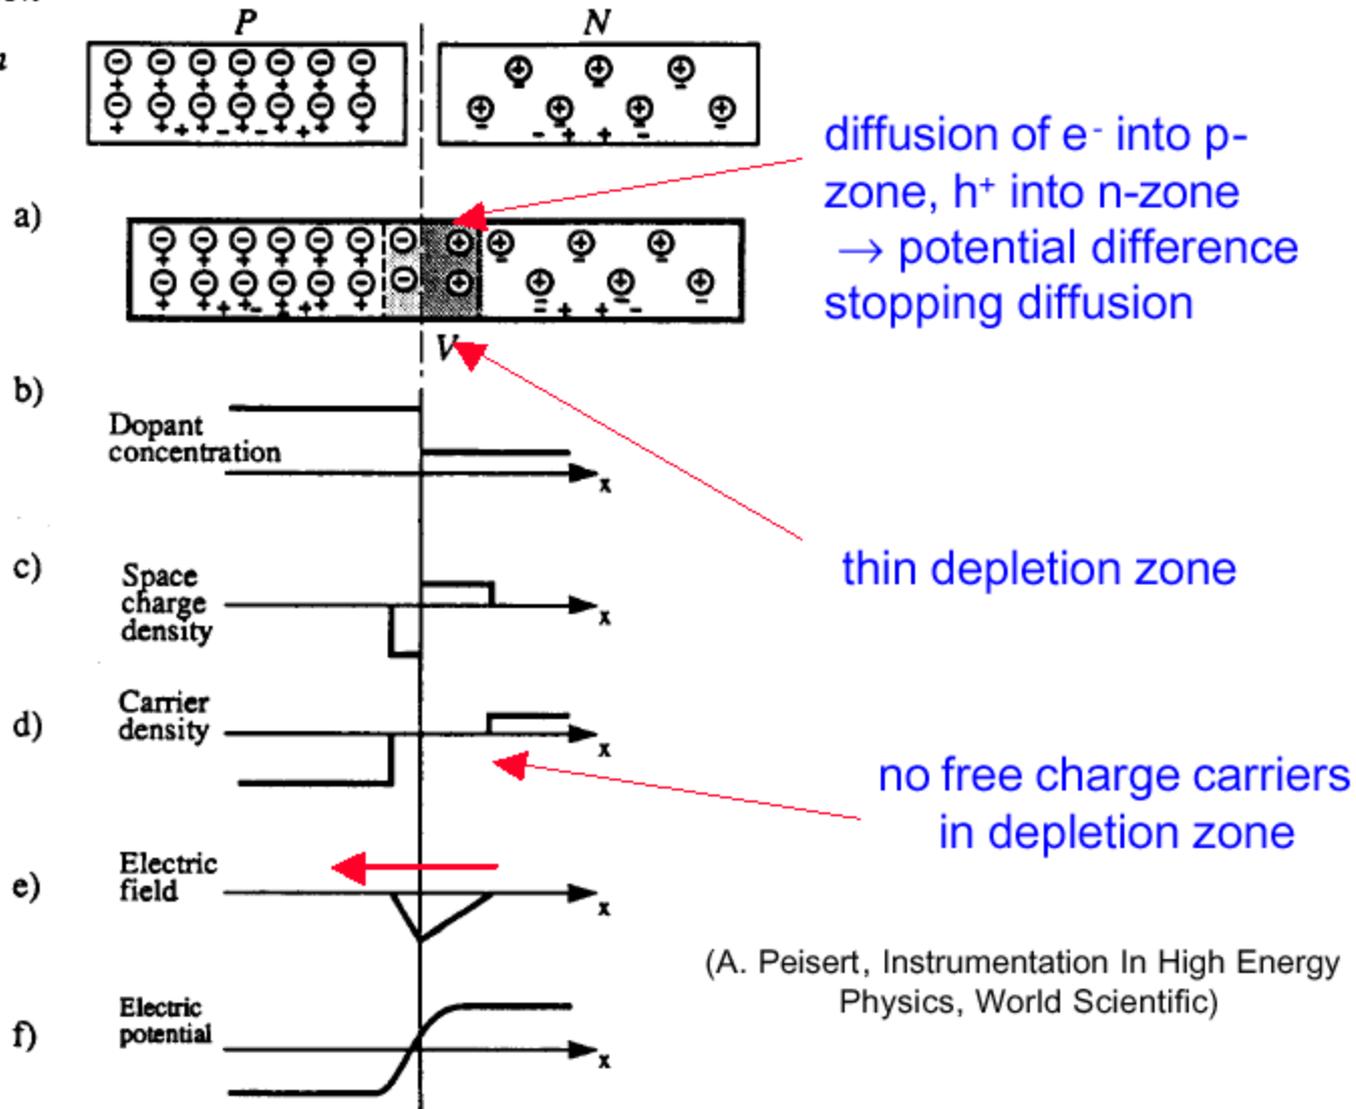

Intrinsic silicon will have electron density = hole density; $1.45 \cdot 10^{10} \text{ cm}^{-3}$ (from basic semiconductor theory).

In the volume above this would correspond to $4.5 \cdot 10^8$ free charge carriers; compared to around $3.2 \cdot 10^4$ produced by MIP (Bethe Bloch loss in 300um Si divided by 3.6 eV).

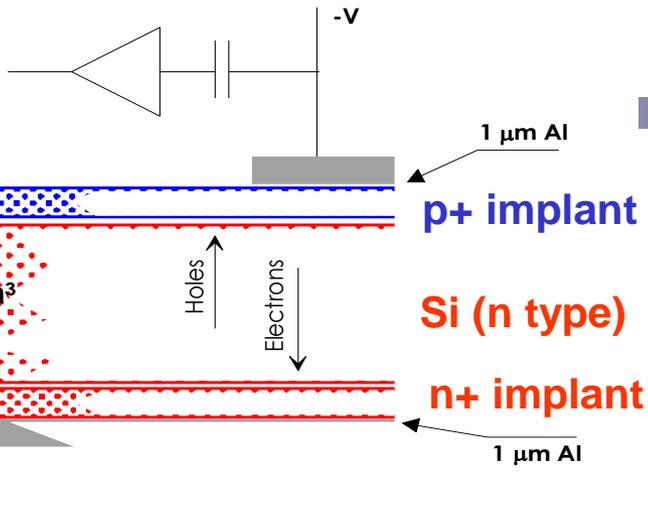

Need to decrease number of free carriers; use depletion zone (reduce temperature would also help but one would need to go to cryogenic temperatures)

Front End electronics

Most detectors rely critically on low noise electronics. A typical Front End is shown below :

where the detector is represented by the capacitance C_d , bias voltage is applied through R_b , and the signal is coupled to the amplifier through a capacitance C_c . The resistance R_s represents all the resistances in the input path. The preamplifier provides gain and feeds a shaper which takes care of the frequency response and limits the duration of the signal.

The equivalent circuit for noise analysis includes both current and voltage noise sources labelled i_n and e_n respectively. Two important noise sources are the detector leakage current (fluctuating-sometimes called shot noise) and the electronic noise of the amplifier, both unavoidable and therefore important to control and reduce. The diagram below shows the noise sources and their representation in the noise analysis :

We now know how most particles (i.e all particles that live long enough to reach a detector; e,u,p, π ,k,n, γ , neutrinos,etc) react with matter.

We now know how to identify particles to some extent, how to measure E and p, v, and how to measure lifetimes using secondary vertices, etc

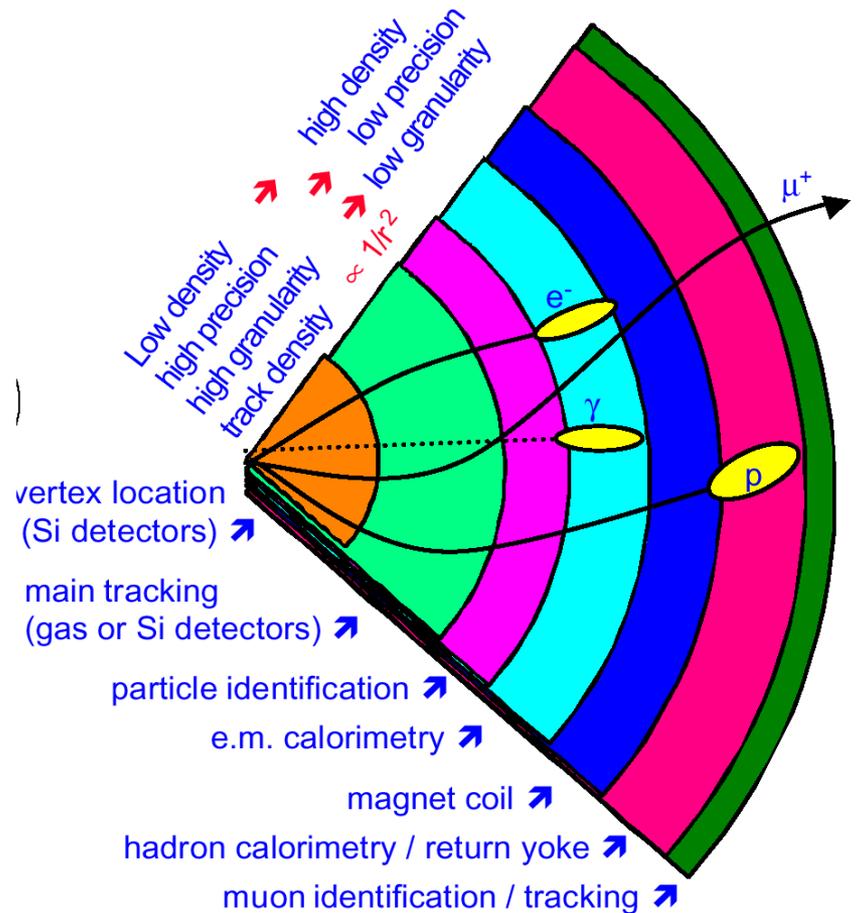

Essential three detector types are used :

1 Ionisation detectors

2 Scintillators

3 Semi Conductors

4 Finally we have looked briefly at how electrical signals are treated in FE electronics

The detector-types mentioned are either for tracking, energy measurement, photon detectors, etc in various configurations.
