# Outline

- Neutrino signal from the Milky Way
- Estimating the neutrino flux
- Description of the analysis method
- ANTARES results

# Neutrino signal from the Milky Way

# Neutrino signal from the Milky Way

- ❑ Cosmic rays interact with interstellar gas
- ❑ Neutrinos produced mainly via charged pion decay
- ❑ Pions do not interact before decay
  - Neutrino spectrum follows CR spectrum
- ❑ Guaranteed signal
- ❑ IceCube excess could be caused by this mechanism
  - Neronov et al. Phys. Rev. D, 89 (103002), 2014

# Estimating the neutrino flux

## 1. Theoretical models

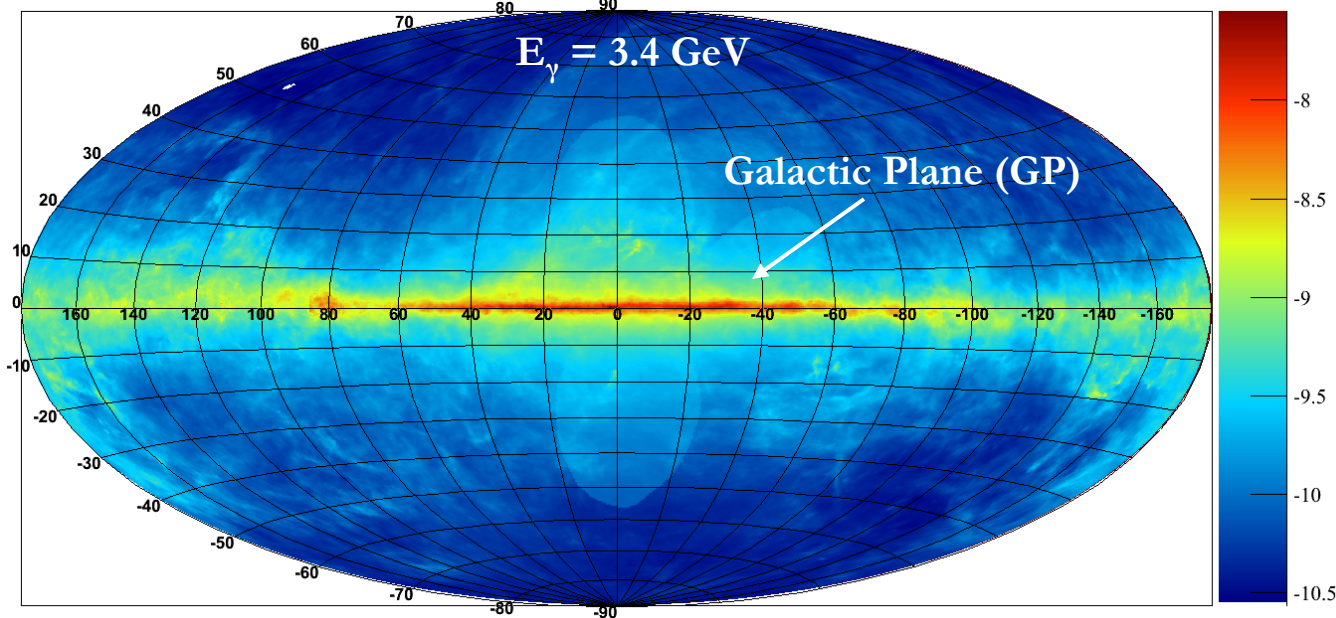

Model name	Reference	Matter density	Cosmic ray flux
NoDrift_simple	Ingelman and Thunman arXiv:hep-ph/9604286	constant: 1 nucleon / cm <sup>3</sup>	constant
NoDrift_advanced	Candia and Roulet JCAP09(2003)005	constant: 1 nucleon / cm <sup>3</sup>	constant
Drift	Candia JCAP11(2005)002	Radially dependent	Higher in GC due to drift of CRs

# Estimating the neutrino flux

## 2. Use experimental data

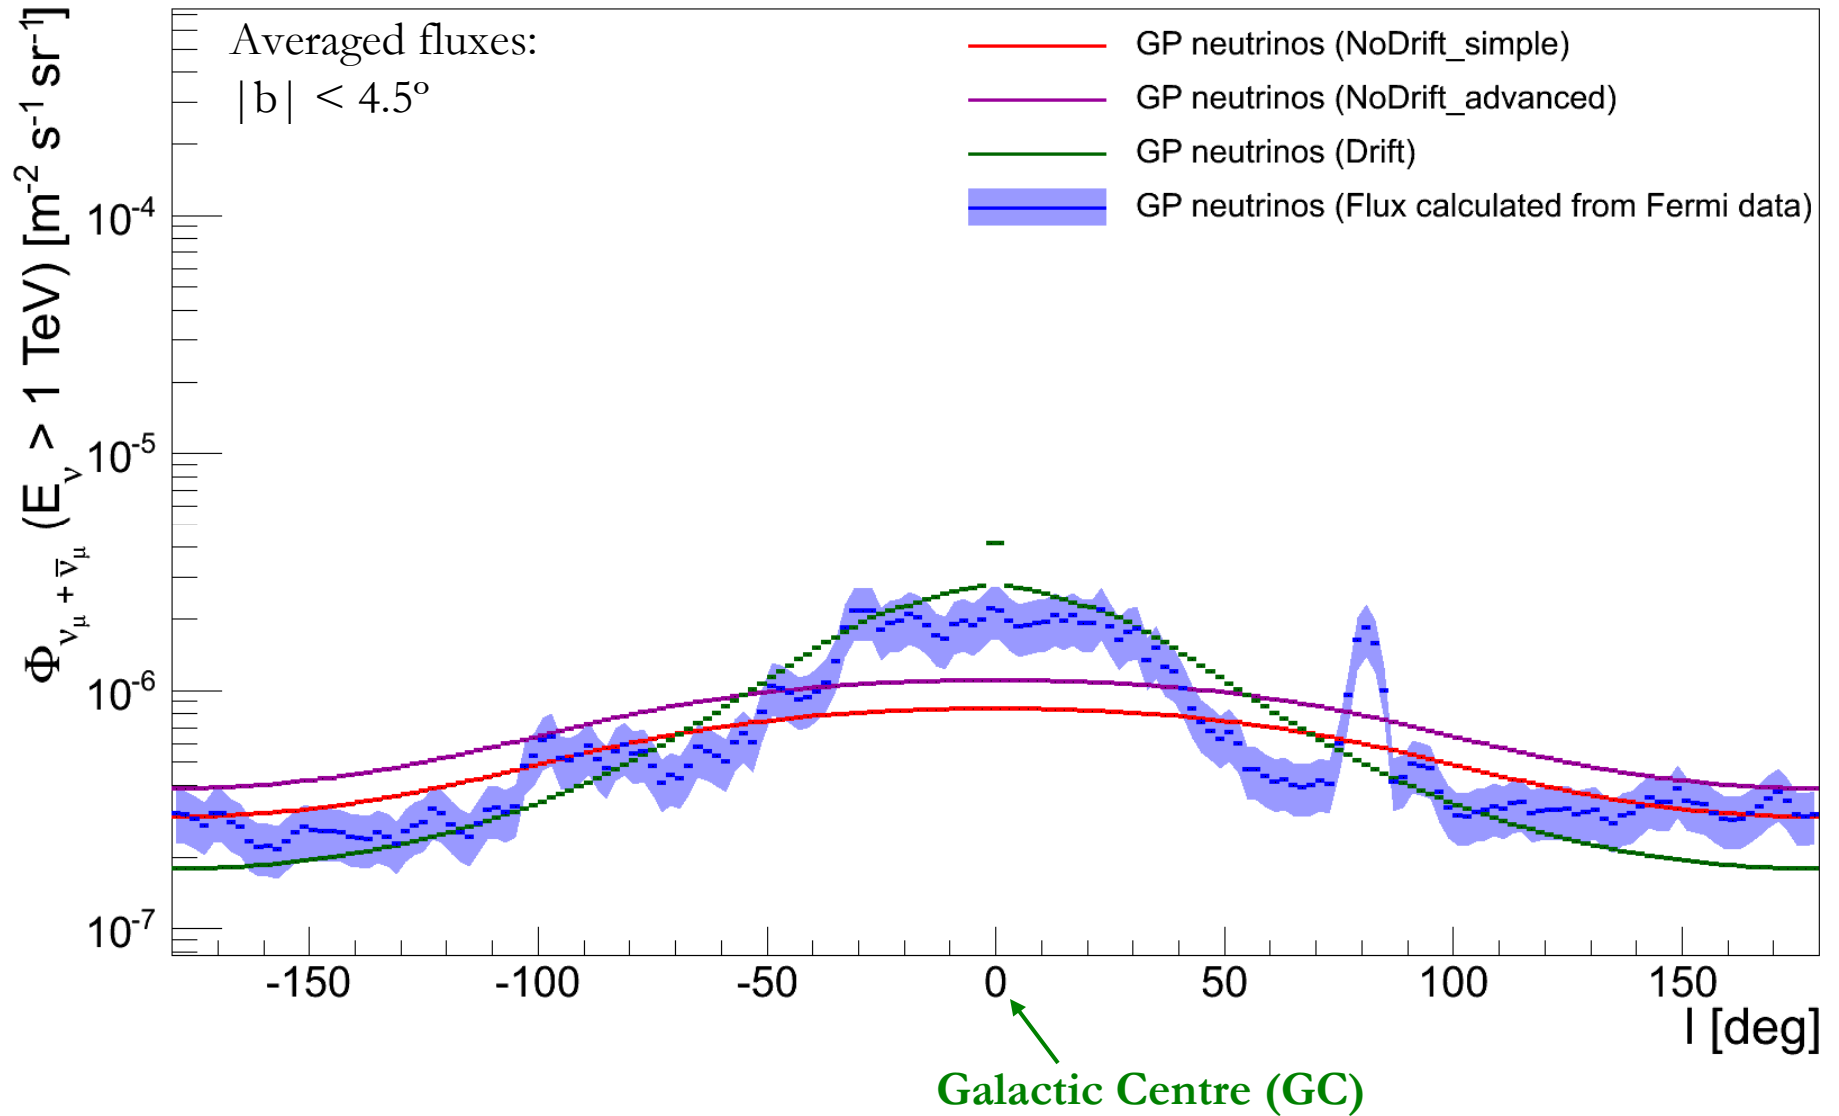

Fermi diffuse flux:

- Use GALPROP to estimate fraction of  $\gamma$ 's from neutral pion decay and IC scattering
  - Ackermann et al. ApJ, 750 (3), 2012
- Uncertainty of neutral pion contribution is estimated from range in models
- Convert neutral pion to charged pion flux

# Estimating the neutrino flux

# The ANTARES neutrino telescope

# The analysis

- Optimise size of signal region for best flux limit (MRF method)

MRF versus longitude and latitude bound (NoDrift\_simple):

MRF versus longitude and latitude bound (NoDrift\_advanced):

MRF versus longitude and latitude bound (Drift):

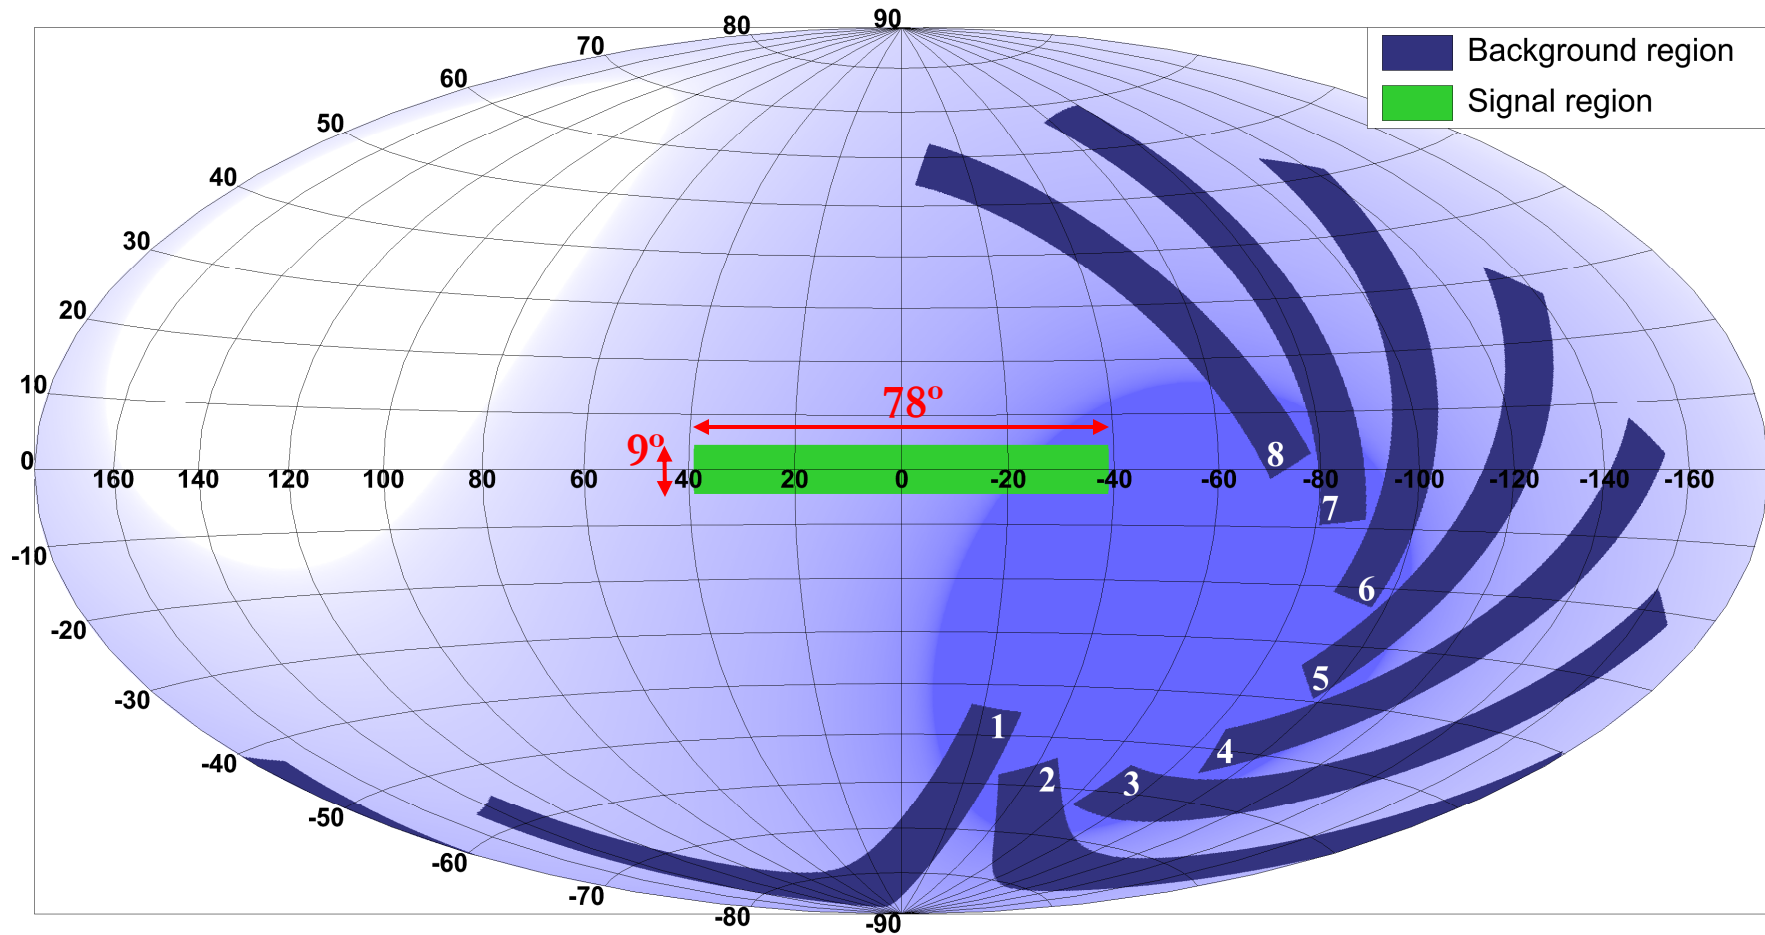

MRF versus longitude and latitude bound (Flux calculated from Fermi data):

# The analysis

Size of each region is 0.214 sr

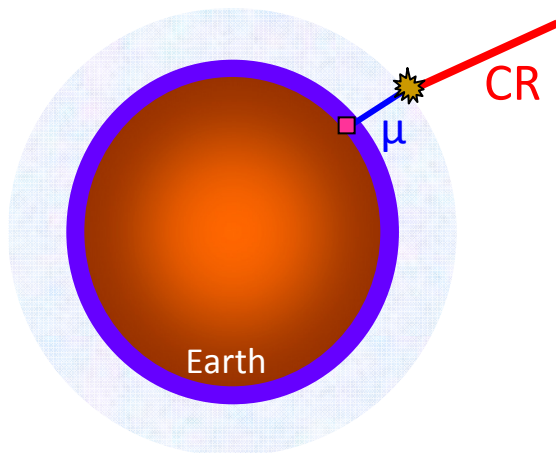

- Background is measured from the data and compared to number of events from the signal region

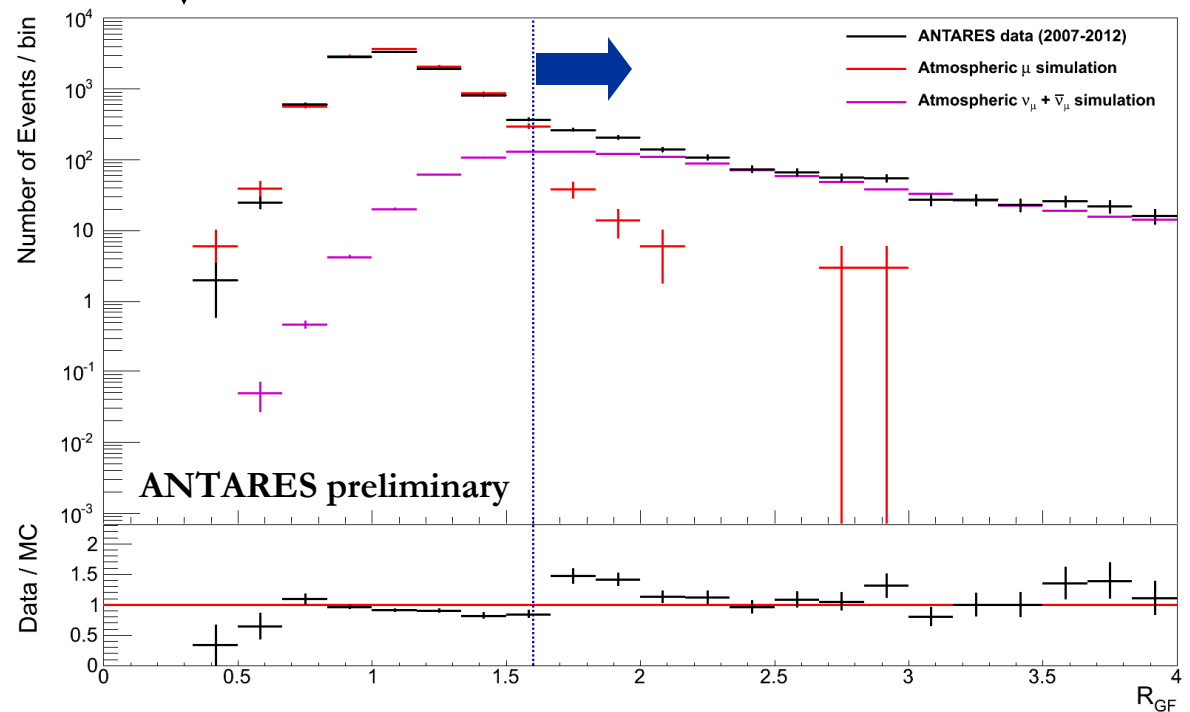

# The background

## 1. Atmospheric muons

- ❑ Reducible background
- ❑ Only consider high quality, upgoing events

Parameter	Description	Cut value
$\beta$	angular error estimate	$< 8.0^\circ$
$R_{GF}$	event topology	$> 1.6$
$\Lambda$ (default trigger)	fit quality	$> -5.62$
$\Lambda$ (low energy trigger)	fit quality	$> -5.57$

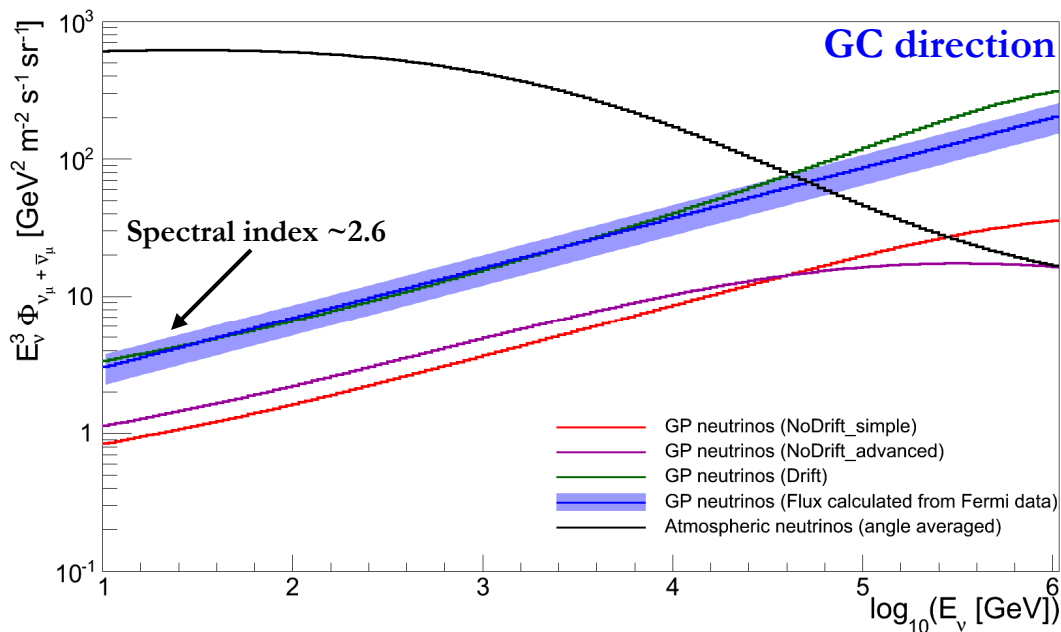

# The background

## 1. Atmospheric muons

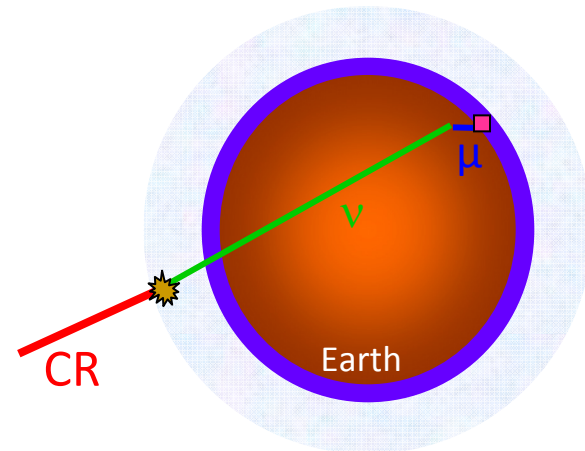

- ❑ Reducible background
- ❑ Only consider high quality, upgoing events

## 2. Atmospheric neutrinos

- ❑ Irreducible background
- ❑ Use energy estimator to suppress

Trigger	$E_{\text{rec}}$ [GeV]
Default trigger	> 350
Low energy trigger	> 250

# ANTARES results

Used data: 2007 – 2012

- Signal prediction:  $\sim 0.6 - 1.8$  events

# ANTARES results

Used data: 2007 – 2012

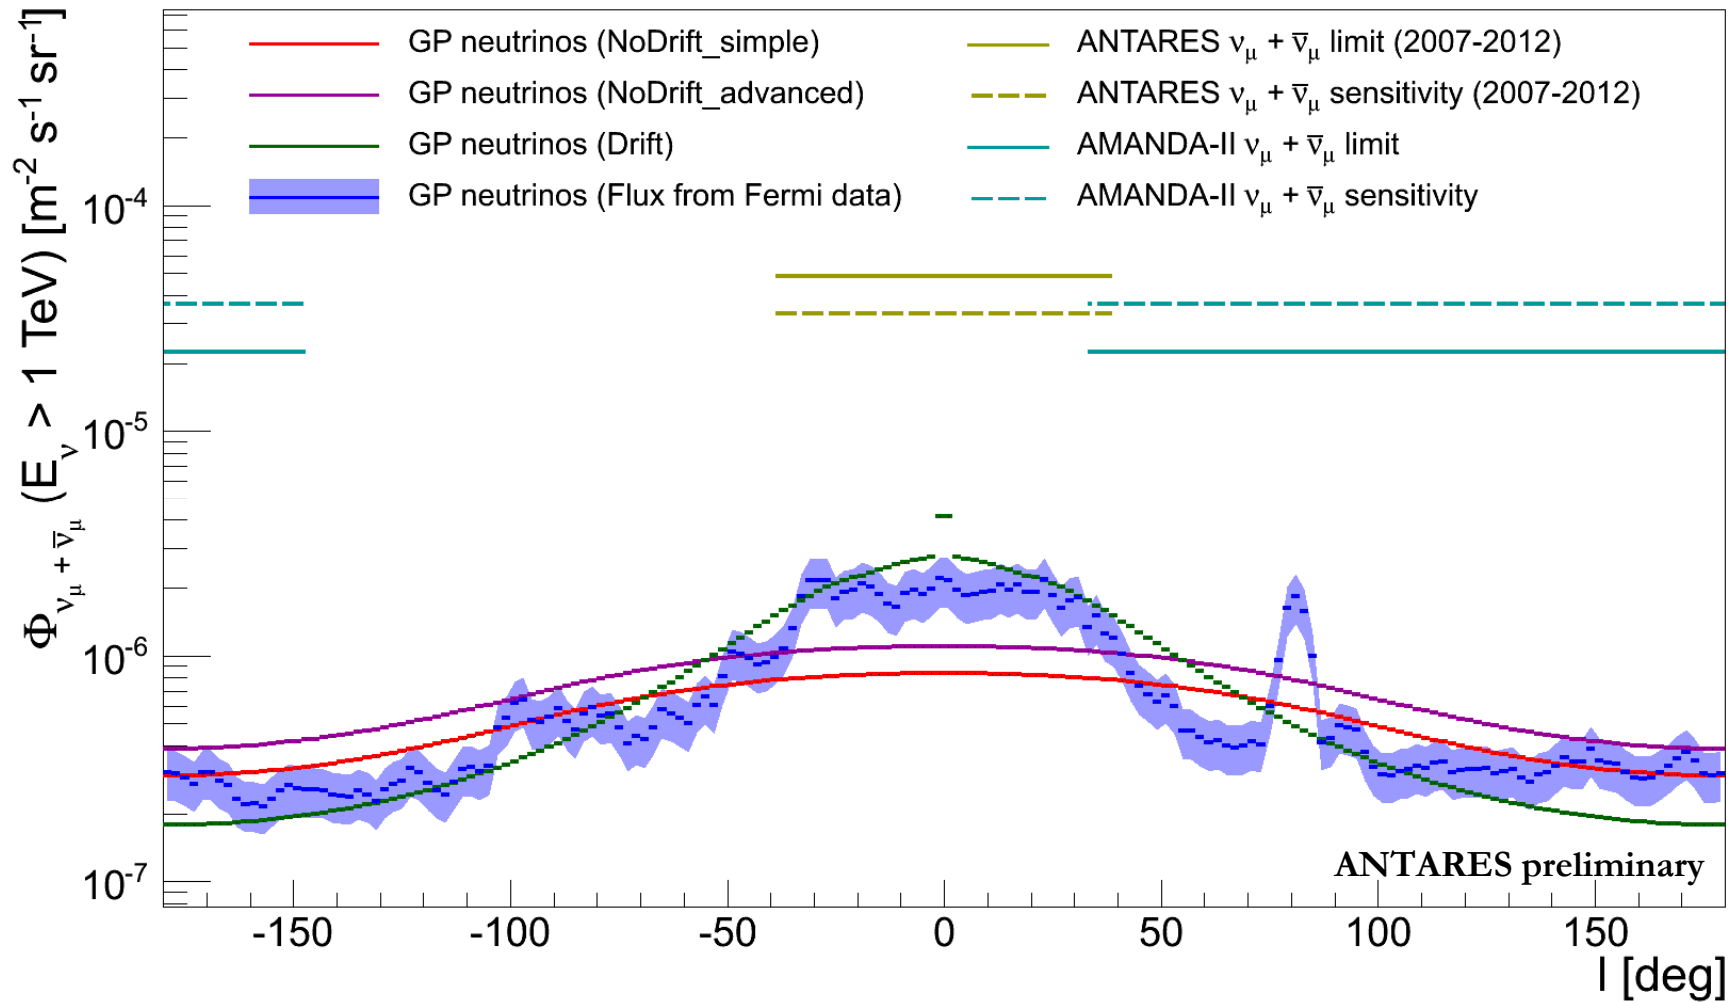

- Signal prediction:  $\sim 0.6 - 1.8$  events
- Excess corresponds to  $0.8\sigma$

# ANTARES results: flux upper limits

■ Flux limit:  $\Phi_{\nu_\mu + \bar{\nu}_\mu} < 4.61 E^{-2.6} \text{GeV}^{-1} \text{m}^{-2} \text{sr}^{-1} \text{s}^{-1}$  (178 GeV < E < 70.8 TeV)  
 central 90% of the signal

# ANTARES results: flux upper limits

■ Flux limit:  $\Phi_{\nu_\mu + \bar{\nu}_\mu} < 10.18 E^{-2.7} \text{ GeV}^{-1} \text{ m}^{-2} \text{ sr}^{-1} \text{ s}^{-1}$  ( $153 \text{ GeV} < E < 52.1 \text{ TeV}$ )  
 central 90% of the signal

---

# Conclusions and outlook

- Measurement of (muon) neutrino flux from cosmic ray interactions in the Milky Way has been performed
- Small excess seen, compatible with background fluctuation ( $0.8\sigma$ )
- Flux upper limits have been set
- KM3NeT will be able to improve limits

# Theoretical models

**Assumption 1:  
cosmic ray flux**

DISK SYMMETRIES

axisymmetric spiral (ASS)

HALO SYMMETRIES

dipole

bisymmetric spiral (BSS)

quadrupole

**Assumption 3:  
magnetic field**

- **NoDrift\_simple model**
  - Constant matter density
  - Neglect magnetic field
  
- **NoDrift\_advanced model**
  - + Take CR composition into account
  
- **Drift model**
  - + Magnetic field gives drift of CRs to GC
  - + Model the matter density
