

Observations of Gamma-Ray Bursts with the HAWC observatory

Dirk Lennarz
Georgia Tech
23rd of June 2014

Gamma-Ray Bursts (GRBs)

- Central engine (collapse of massive star, merger of two compact stellar remnants)
- Collimated relativistic outflow
- Internal and external shocks
- Prompt keV-MeV emission
- Afterglow emission

Radiation mechanism

- Synchrotron Emission
- Inverse Compton Radiation

Distinguishable by emission at the highest energies

Data Acquisition Systems

- Triggered (“main”) DAQ
 - Records time and charge of individual PMT pulses
 - Reconstruction of individual gamma-rays
- Scaler DAQ
 - PMT pulse counting mode
 - Detects GRBs from statistical excess over noise rate

GRB 130427A

- Brightest burst ever detected by *Swift*
- Very close ($z=0.34$)
- Most powerful GRB detected $z < 0.5$

Science 343 (2014) 48-51

GRB 130427A

- Brightest burst ever detected by *Swift*
- Very close ($z=0.34$)
- Most powerful GRB detected $z < 0.5$
- Longest lasting high energy emission ever detected (~ 20 h)
- Most energetic photon ever detected (95.3 GeV)

➔ Evidence for inverse Compton?

Science 343 (2014) 42-47

What did HAWC see?

Misfortune 1

- The main DAQ was offline
 - Luckily, the scaler DAQ was taking data
- ➡ Monitoring the rate of 29 tanks (HAWC 30) with 112 PMTs

Misfortune 2

- The GRB had an elevation of only 33° in the HAWC field of view
- ➡ Sensitivity is about 2 orders worse than at zenith
- ➡ Increased energy threshold

GRB 130427A Upper Limits

HAWC 30,
close to
zenith: $\sim 2.3 \sigma$

Full HAWC,
close to
zenith: $> 15 \sigma$

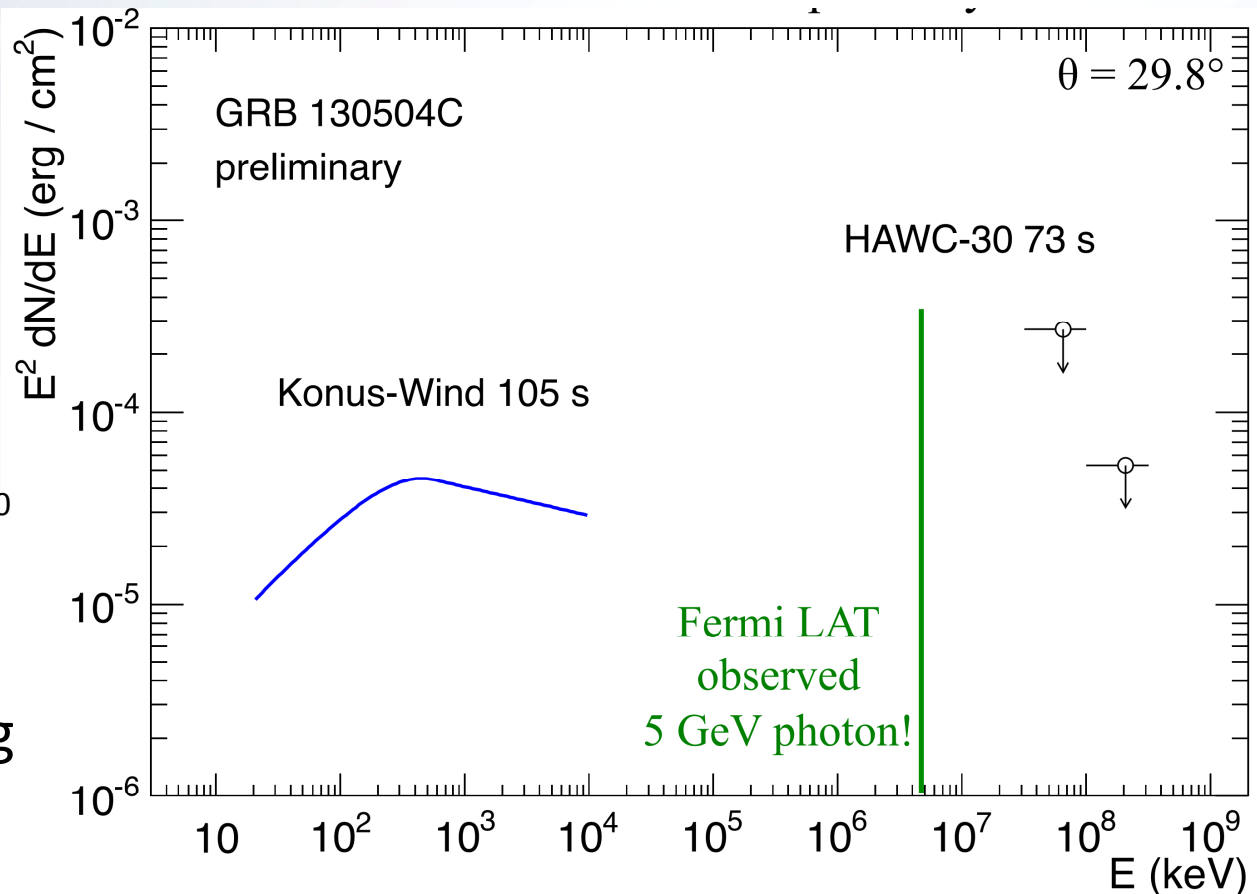

Main DAQ

Quick look analysis

- Single time-bin analysis
- Estimate background from off-time data
- Counts number of events in T_{90} and $3 \times T_{90}$
- If excess $< 5\sigma$ keep data blind

➔ Currently installing at site

➔ Provide alerts / positions to the community via GCN

Credit: D. Zaborov

Main DAQ

Likelihood analysis

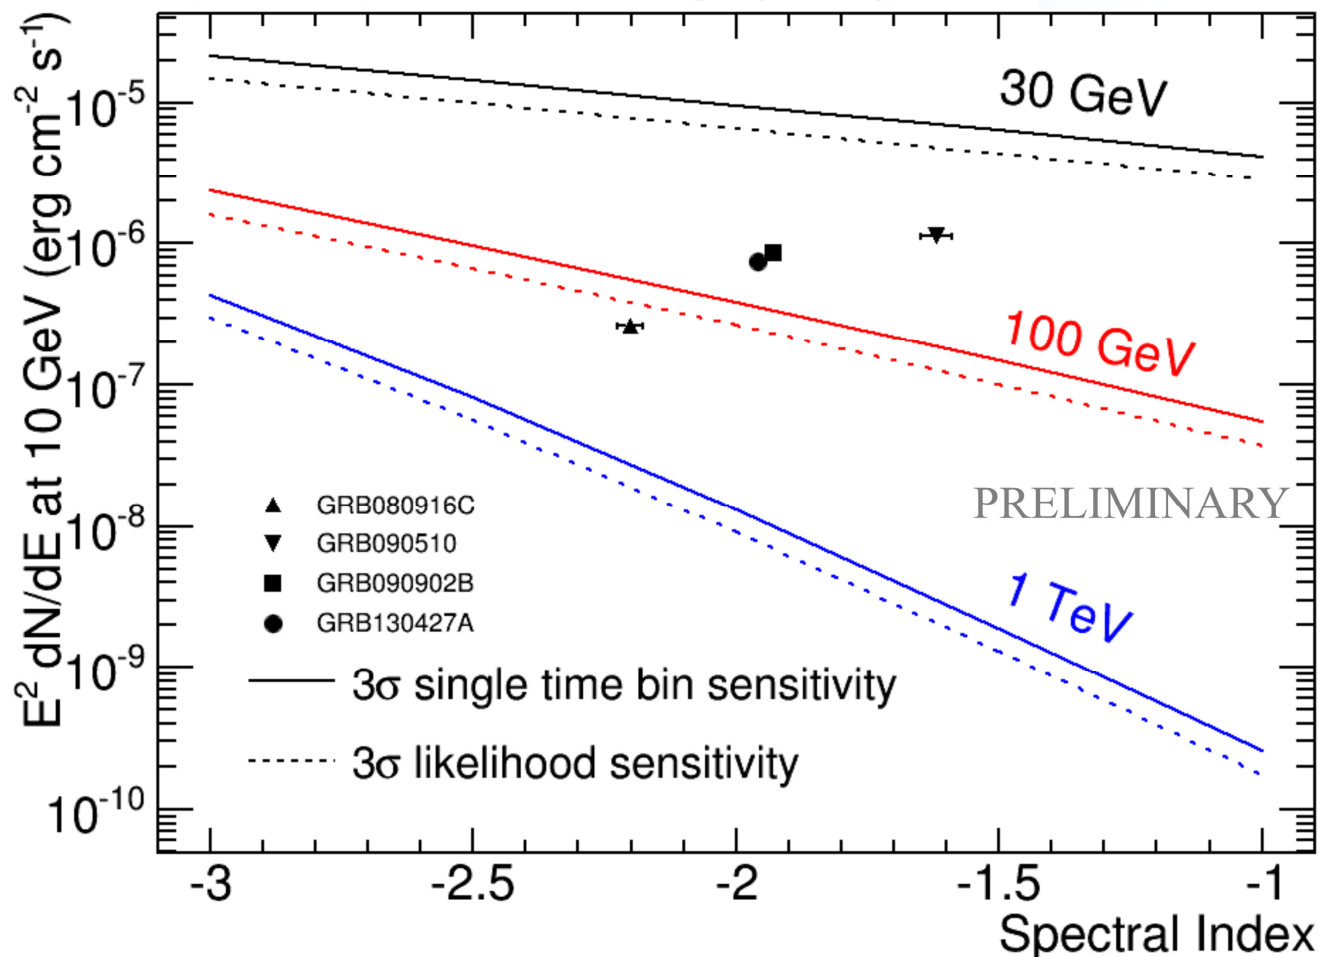

- Fermi: GeV emission delayed + temporally extended
- Add this knowledge to signal Likelihood

➔ Crystal Ball Function

Sensitivity

3σ discovery sensitivity to sources with sharp high-energy cutoffs

- Likelihood $>30\%$ more sensitive
- **HAWC will be able to see bursts comparable to those already observed**

Note: Reference GRB flux is scaled according to main DAQ duration sensitivity.

HAWC Combined Power

Abeysekara et al., Astropart. Phys. 35 (2012) 635

- Simulated GRB (black triangle)
- Green band: flux values from both DAQs agree within 25%

Assumptions

- >1 GeV emission: additional hard (long E^{-2} , short $E^{-1.66}$) power-law
- Power-law cutoff by EBL absorption
- Long GRB T_{90} fluence ratio 10%, short GRBs 100%

Cutoff	main DAQ sGRB /yr	Scaler sGRB /yr	main DAQ LGRB /yr
n/a	1.4	0.15	0.25
500 GeV	1.3	0.12	0.22
400 GeV	1.2	0.11	0.20
300 GeV	0.97	0.10	0.15
200 GeV	0.54	0.07	0.08
150 GeV	0.27	0.05	0.04
100 GeV	0.07	0.02	0.01

➡ Detection rate as high as 1.63 GRB per year!

Summary

- HAWC is an exciting new gamma-ray experiment
- GRB 130427A was a very special GRB, but under unfavourable conditions for HAWC
- HAWC has the sensitivity to detect GRBs at the highest energies
- Detection rate might be as high as 1.6 GRBs per year!

Time Windows

1. 0-20 s (first two BAT emission periods)
2. -5-55 s (extended time window)
3. -5-145 s (GBM $T_{90}=138\text{s}$)
4. 120-300s (third BAT emission period)
5. -10-290s (combine all three BAT emission periods)
6. -10-10s around time of highest energy LAT photon
7. 11.5-33s (Fermi-LAT extra hard power law)
8. 196-257s (Fermi-LAT power law harder than -2)
