Dark Matter

Direct DM detection

Indirect DM detection

Conclusions

Dark matter only simulations:

- No baryons.
- Cusped DM profile.
- Too many satellites and too-big-to-fail problem (c.f. A. Brooks' plenary talk).

Cosmological hydrodynamic simulations until recently:

- Small disk / too massive bulge (angular momentum problem).
- Too massive stellar disks at $z=0$ \leftarrow too early SFH.
- Too peaked rotation curves.

Goal of this work: \rightarrow Address this problem (with RAMSES package). (See also Guedes et al. (2011), Stinson et al. (2013), Roskar et al. (2014), Marinacci et al. (2014), Hopkins et al. (2014), Agertz & Kravtsov (2014), Vogelsberger et al. (2014), Crain et al. in prep.)

\rightarrow Use the obtained Milky-Way-like simulation as a consistent framework for astroparticle calculations (no \pm ad-hoc/simplified considerations like spherical NFW profile or Maxwellian DM velocity distribution...).

RAMSES (Teyssier 2002)

This code is a grid-based hydro solver with adaptive mesh refinement.

Idea: use the Particle-Mesh algorithm on a set of adaptively refined grid.

Method:

each cell is recursively refined if the number of particles per cell exceeds some threshold.

Hydrodynamics: Godunov scheme.

Figure : Adaptive Mesh Refinement

Star formation and supernova feedback

Star formation

- Infall of cold gas \rightarrow stars.
- Model the gas conversion into stars by a Schmidt law

$$\dot{\rho}_g = -\epsilon_{ff} \frac{\rho_g}{t_{ff}} \text{ for } \rho > \rho_0$$

with

- t_{ff} local free-fall time.
- ρ_0 threshold density, equal to density defined by gas treatment.
- ϵ_{ff} star formation efficiency, set to low value (1 %).

\rightarrow Transform gas into star particles.

SN feedback:

- Type II SN, relevant for stellar masses $\approx 8 - 40 M_{\odot}$.
- Short living stars.
- 10 Myr after the star (particle) creation : explosion.
- 20 % of the star mass is re-injected into the gas (corresponding to a Chabrier IMF).
- Energy per explosion $\approx 10^{51}$ erg.
- Dissipation of SN energy time scale = 20 Myrs.
- GMC model: More rare but more powerful explosions avoid an artificially concentration of SN feedback.
- Reheats the gas. Balance between star formation and SN feedback.
- Drives central dark matter density (c.f. A. Brooks' talk).
- Related to Cusp/Core question and direct/indirect dark matter detection.

Milky Way-like Halo

Run	R_{97} (kpc)	$M_{97,\text{tot}}$ (10^{10})	$M_{97,\text{gas}}$ (10^{10})	M_* (10^{10})	$M_{97,\text{dm}}$ (10^{10})	R_{200} (kpc)	$M_{200,\text{tot}}$ (10^{10})
A	344.9	227.52	23.96	18.23	185.32	253.69	186.68
A-DM	329.28	19.79				243.53	165.13
B	233.99	71.04	7.96	5.58	57.49	176.47	62.83
B-DM	220.85	59.73				162.90	49.42
C	244.60	81.15	9.58	5.50	6.60	181.83	68.73
C-DM	236.41	73.27				176.01	62.35

Primary numerical parameters of the simulated halos at $z = 0$, A, B and C referring to the hydrodynamical versions and *-DM to the corresponding dark matter only simulations. We show the radius of the sphere whose mean density is equal to 97 (respectively 200) times the critical density of the universe at redshift 0. The further columns give the total mass and DM mass inside R_{97} , the gas mass and stellar mass inside $R_{97}/10$. The corresponding numbers of gaseous cells, star particles, and DM particles are given next. In all the runs, the spatial resolution reaches 150 parsec at $z = 0$.

Halo C

DM-only Run: dark matter profile

- Best fitting values for the spherical averaged density profiles fitted with equation $\rho(r, \rho_s, r_s, \alpha, \beta, \gamma) = \frac{\rho_s}{(\frac{r}{r_s})^\gamma (1 + (\frac{r}{r_s})^\alpha)^{(\beta - \gamma)/\alpha}}$. For the DM-only simulations, we fixed $\alpha = 1$. The fit was performed for $r \in [250\text{pc}, R_{97}]$.

Run	$\text{Log}_{10}\rho_s$ [kpc^3]	r_s [kpc]	α	β	γ

Direct detection

The dark matter results of the simulation = Realistic and consistent Milky-Way-like framework for astroparticle calculations!

$$\frac{dR}{dE_R} = \frac{\rho_{\text{DM}}}{M_{\text{DM}}} \frac{d\sigma}{dE_R} \eta(E_R, t)$$

Particle and nuclear physics:

Astrophysics:

$$\frac{d\sigma}{dE_R} = \frac{M_N}{2\mu_n^2} \sigma_n^0 \frac{(f_p^2 Z + (A - Z) f_n^2)^2}{f_n^2} F^2(E_R) \quad \eta = \int_{v_{\min}}^{v_{\text{escape}}} d^3\vec{v} \frac{f(\vec{v})}{|\vec{v} - \vec{v}_{\text{earth}}|}$$

Features?

Maxwellian?

v_{\min} ? v_{escape} ?

Conclusions

Indirect Detection

Background model for cosmic rays: Use SN feedback, star and gas distribution to calculate diffuse hadronic gamma emission.

Star distribution → SNII explosion → cosmic rays.

Gas distribution → CR spallation → gamma fluxes.

SN feedback

- IMF 20% → massive stars.
- Age = 10 Myr (Type SN II).
- Energy per explosion : 10^{51} erg.
- 20% used as feedback energy.

SN II = Cosmic Ray sources

- Select all SN events in the past 500 Myr (typical residence time of CRs in the Galaxy).
- Explosion rate (at redshift 0) ~ 4 Msun/year.
- 10% converted into high energy cosmic rays with a power law energy spectra : E^{-2} .

Conclusions

Conclusions

Summary:

- Zoom simulations with RAMSES.
- One halo/galaxy exhibits a lot of MW observational properties.
- Interplay between star formation and SN feedback → Impact on dark matter profile (we obtained a cored DM profile).
- Caveat with star formation history → need for a different/additional feedback scheme?
- Local dark matter: Adiabatic contraction and corotating dark disk.
- Analyse of satellites: Halo in lower MW mass range seem to agree with MW observations.

Perspectives:

- Improvement of spiral galaxy simulations: new (more exact) treatment of gas physics intervening in star formation or (and?) new feedback schemes?
- Consistent framework for astroparticle calculations related to (direct and indirect) dark matter detection.
