## Status of observations of PWNe and SNRs in the gamma-ray regime

*Wednesday, June 25, 2014 2:00 PM (20 minutes)*

The last few years have witness a revolution in very high gamma-ray astronomy (VHE;  $E > 100$  GeV) driven largely by a new generation of Cherenkov telescopes. These new facilities, namely H.E.S.S. and the new 28-meter-sized mirror H.E.S.S. 2, MAGIC and its upgrade MAGIC 2 and Veritas were designed to increase the flux sensitivity in the energy regime of hundreds of GeV, expanding the observed energy range from 100 (50) GeV to multi-TeV, and fostered as a result a period of rapid growth in our understanding of the Non-Thermal Universe. As a result of this fast development the number of new VHE Galactic sources detected has increased from a few in the early 90's to nearly 50 Galactic sources nowadays. A review of the most recent Galactic VHE results will be discussed, emphasizing in particular results concerning Pulsar Wind Nebulae and Supernova Remnants, the most numerous TeV galactic population and the expectations for the future observatory CTA.
