

Measurement of properties of the Higgs boson in bosonic decay channels using the ATLAS detector

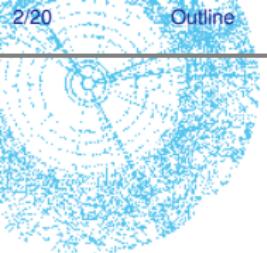

Alberto Palma

on behalf of the ATLAS Collaboration

LIP & FCUL, Lisbon

PASCOS 2013

Taipei, 20th –26th November, 2013

Outline

❑ Introduction

- ❑ Production and decay modes
- ❑ Channels overview
 - ❑ Selection
 - ❑ Event categories
 - ❑ Backgrounds

❑ Properties (see also the talk of Florian Bernlochner)

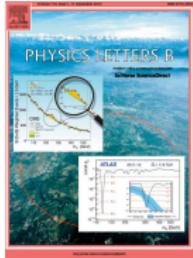

- ❑ Mass
- ❑ Coupling strengths
- ❑ Production mechanisms

❑ Summary

Introduction

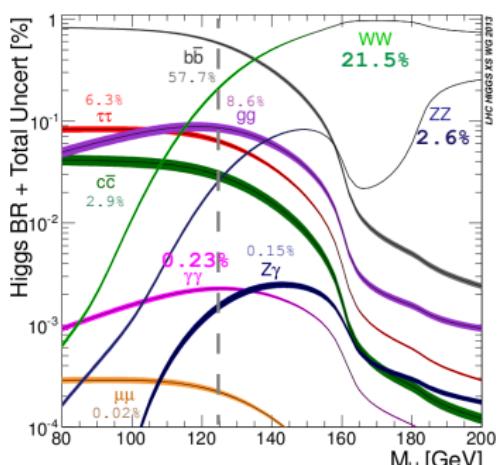

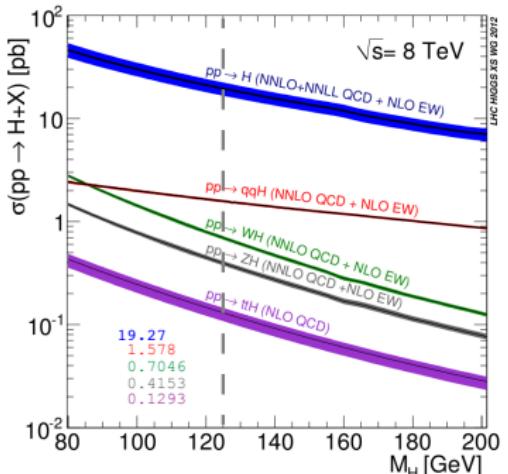

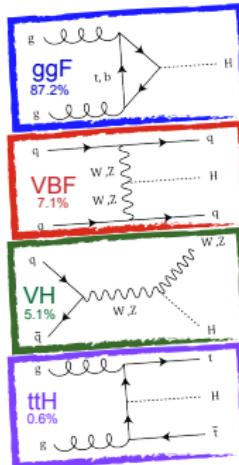

- ❑ Most striking result from ATLAS and CMS experiments, so far:
4th July, 2012: "*Observation of a new particle in the search for the Standard Model Higgs boson with the ATLAS detector at the LHC*"

- Since then: compare the properties of the new particle with the SM predictions for the Higgs boson:
 - "Measurements of Higgs boson production and couplings in diboson final states with the ATLAS detector at the LHC"
[Phys. Lett. B 726 (2013), pp. 88-119]
 - "Evidence for the spin-0 nature of the Higgs boson using ATLAS data"
[Phys. Lett. B 726 (2013), pp. 120-144]
 - Other topics:**
couplings to fermions, differential cross section,...

Production and decay

- ❑ $\Gamma_H \simeq 4 \text{ MeV} @ m_H = 125 \text{ GeV}$
- ❑ $H \rightarrow WW$: allow a broad range of masses to be “scanned”
- ❑ $H \rightarrow ZZ/\gamma\gamma$: distinct signatures, but low statistics

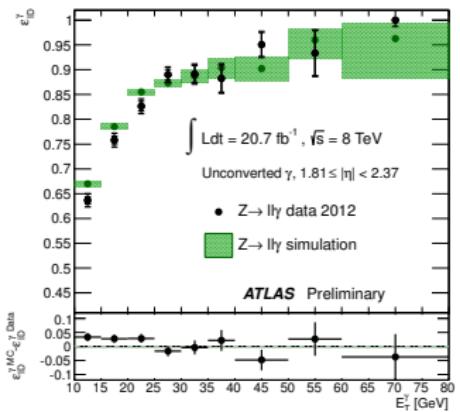

- ❑ Couplings determined by the mass: $g_{Hff} = \frac{m_f}{v}; g_{HV\bar{V}} = \frac{2m_V^2}{v}; \dots$

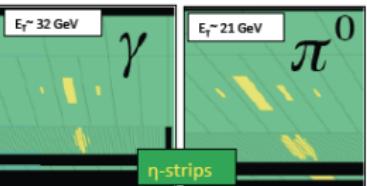

$H \rightarrow \gamma\gamma$ overview

 $\mathcal{L} = 20.7(4.7) \text{ fb}^{-1}$ (2012 (2011)), $\sqrt{s} = 8(7) \text{ TeV}$

- ❑ **Simple signature:** pair of high- p_T isolated photons
 - ❑ **Mass:** $m_{\gamma\gamma}^2 = 2p_{\gamma_1} p_{\gamma_2} (1 - \cos \theta) \simeq p_{\gamma_1} p_{\gamma_2} \theta^2$

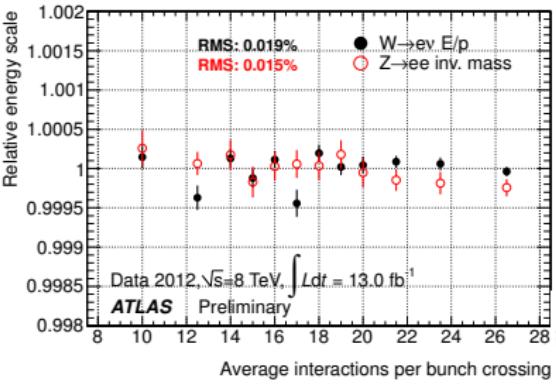

- ★ photon ID: main syst. unc. on signal yield (2.4%)
 $(\epsilon_{ID}(E_T, \eta) \sim 85\% - 95\%, \text{ for } E_T^\gamma > 30 \text{ GeV})$

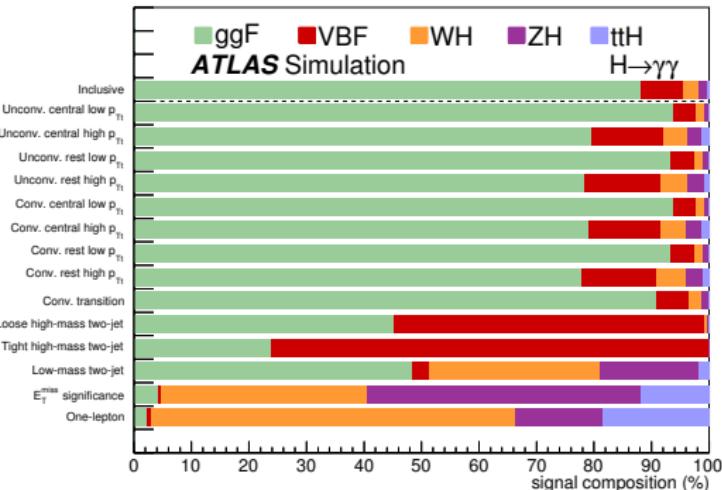

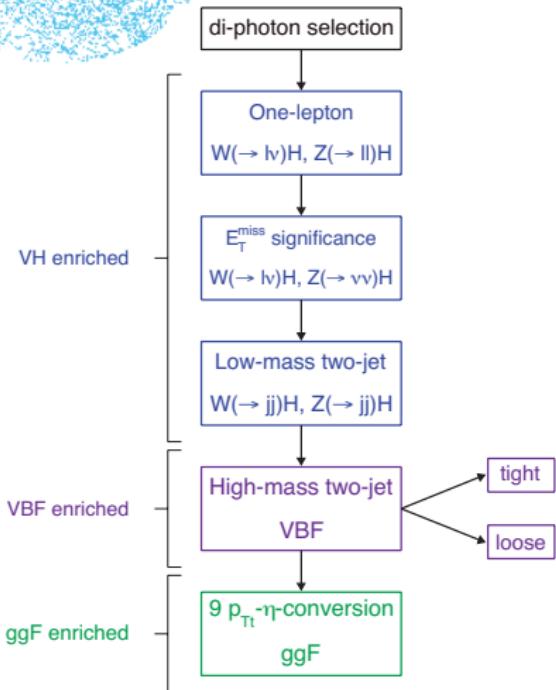

EM calo allows for discriminations
of bkg such as $\pi^0 \rightarrow \gamma\gamma$

- ★ Electron energy scale:
stability with pile-up and with time

$H \rightarrow \gamma\gamma$ sub-channels

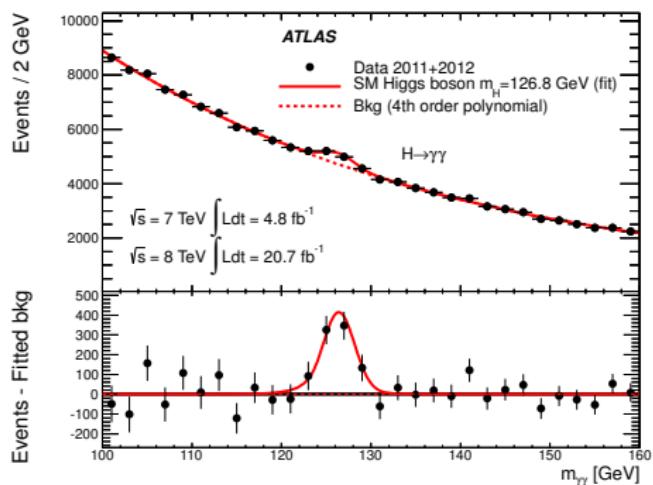

- ❑ Event categorization: increase sensitivity to signal and to separate Higgs production mechanisms

di-photon thrust axis in the transverse plane: $p_{Tt} = |(\vec{p}_T^{\gamma_1} + \vec{p}_T^{\gamma_2}) \times \hat{t}| \leq \hat{t} = (\vec{p}_T^{\gamma_1} - \vec{p}_T^{\gamma_2}) / |\vec{p}_T^{\gamma_1} - \vec{p}_T^{\gamma_2}|$

$H \rightarrow \gamma\gamma$ background

- ❑ Irreducible background: QCD $\gamma\gamma$ production ($\sim 75\%$)
- ❑ Reducible background: γj and jj (jets misidentified as photons), and DY (mis-reconstruction of electrons) ($\sim 25\%$)
- ❑ Shape parameters and the normalization of the background determined by a fit to the data

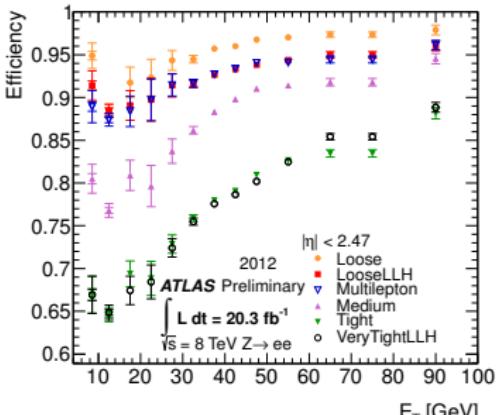

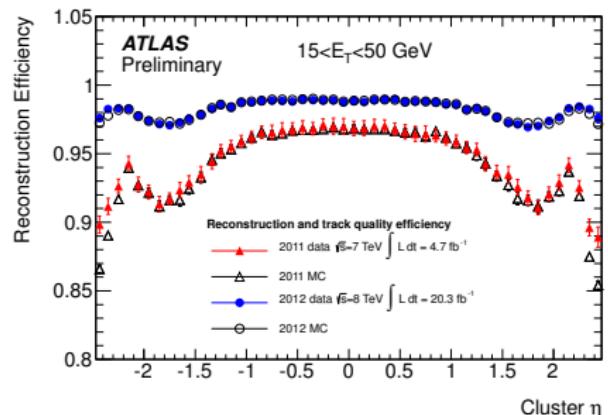

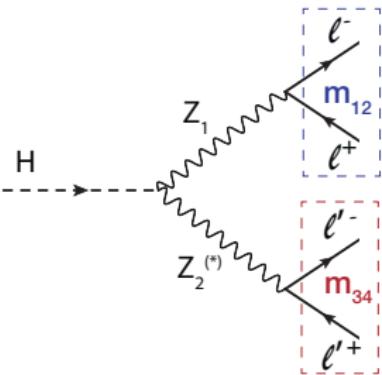

- ★ $m_{\gamma\gamma} = 126.8 \pm 0.2(\text{stat.}) \pm 0.7(\text{syst.}) \text{ GeV}$
- ★ main syst. unc.: photon energy scale
- ★ significance of the observed peak is 7.4σ

$H \rightarrow ZZ^* \rightarrow 4\ell$ overview

- ❑ Signature: 2 pairs of same-flavour, opposite-charged, isolated leptons

- ❑ Leptons assigned to quadruplets of the same flavour and opposite charge, with $p_T > 20, 15, 10 for leading leptons$
- ❑ Electron ID & reco: main syst. unc. on signal yield (2.4% - 9.4%)

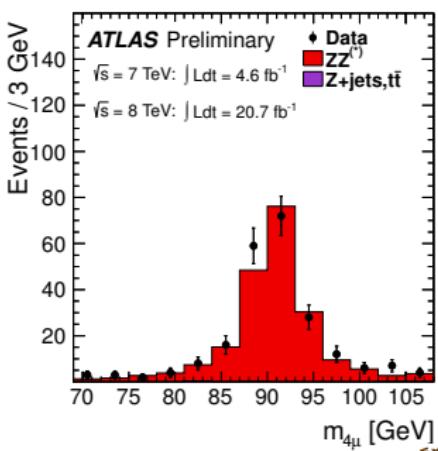

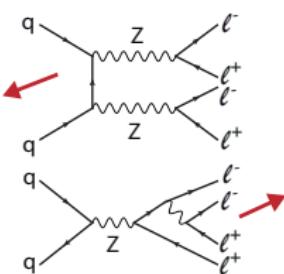

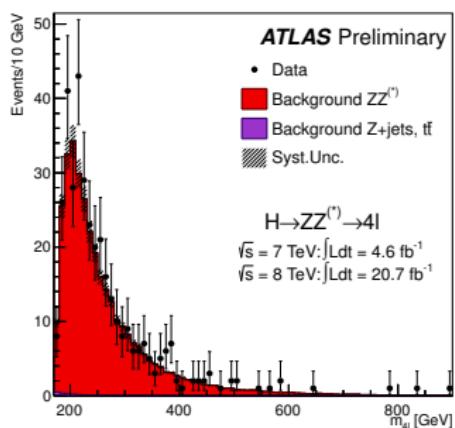

$H \rightarrow ZZ^* \rightarrow 4\ell$ backgrounds

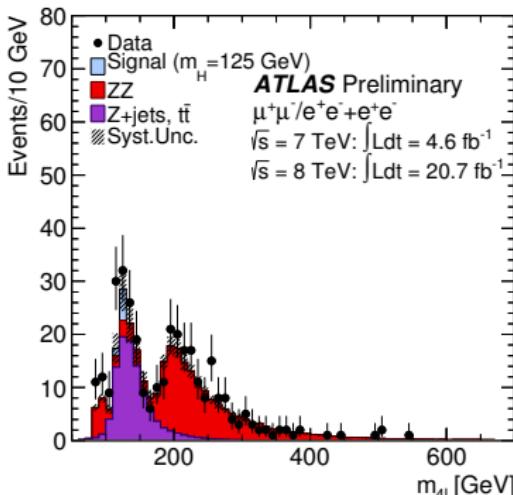

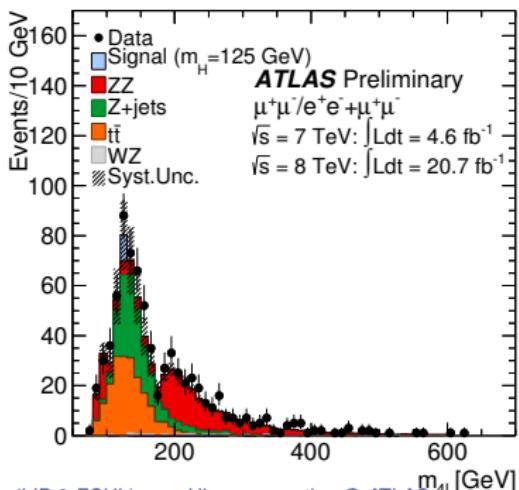

Irreducible: continuum ZZ production is the largest background

- Normalization and $m_{4\ell}$ shape both taken from simulation
- Single resonant Z peak and high mass resonance used to constrain ZZ contribution

$H \rightarrow ZZ^* \rightarrow 4\ell$ backgrounds

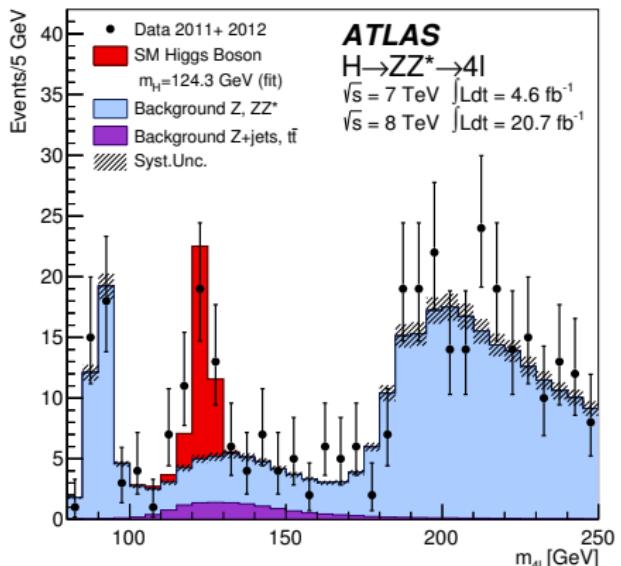

- ❑ Reducible: mainly $Z + \text{jets}$ and $t\bar{t}$ processes (jets faking leptons)
- ❑ composition depends on the flavour of the sub-leading lepton pair ($\ell\ell + \mu\mu$, $\ell\ell + ee$)
- ❑ Approach:
 - ❑ Normalization from data-driven methods: signal yields extrapolated from CRs using transfer factors obtained from simulation control samples
 - ❑ $m_{4\ell}$ shape derived from background simulation using relaxed lepton selection

$H \rightarrow ZZ^* \rightarrow 4\ell$ sub-channels

- Each $H \rightarrow ZZ^* \rightarrow 4\ell$ candidate is assigned to one of the three categories:

- ★ **VBF-like**: 2 high- p_T jets; $|\Delta\eta_{jj}| > 3$; $m_{jj} > 350$ GeV
- ★ **VH-like**: not VBF-like; additional isolated lepton with $p_T > 8$ GeV
- ★ **ggF-like**: not VH- or VBF-like

- ★ $m_{4\ell} = 124.3^{+0.6}_{-0.5}(\text{stat.})^{+0.5}_{-0.3}(\text{syst.}) \text{ GeV}$
- ★ main syst. unc.: lepton energy and momentum scale ($\pm 0.2\% - \pm 0.4\%$)
- ★ significance of the observed peak is 6.6σ

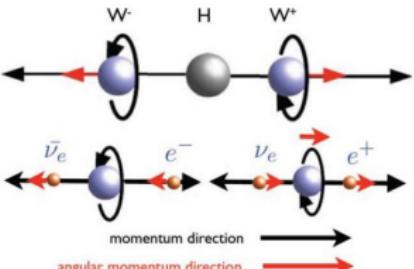

$H \rightarrow WW^* \rightarrow \ell\bar{\nu}\ell\nu$ overview

Signature: 2 oppositely charged isolated leptons and \cancel{E}_T

- $e\mu$ pair: dominates sensitivity to the Higgs boson signal
- same flavour: larger backgrounds (DY)
- cannot reconstruct a narrow mass peak due to neutrinos:

$$m_T = \sqrt{(E_T^{\ell\ell} + \cancel{E}_T)^2 - |\vec{p}_T^{\ell\ell} + \vec{\cancel{E}}_T|^2}$$

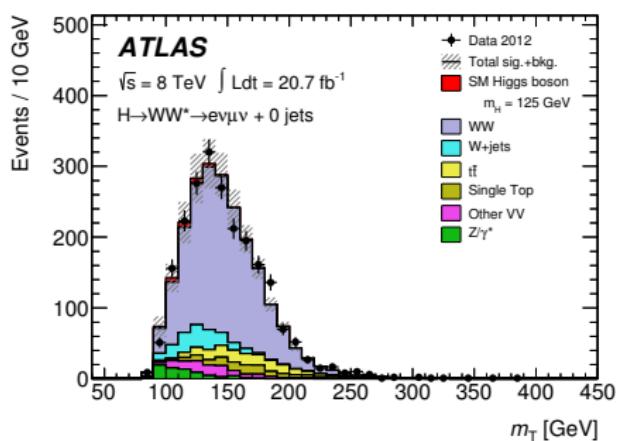

$$\text{(with } E_T^{\ell\ell} = \sqrt{|\vec{p}_T^{\ell\ell}|^2 + m_{\ell\ell}^2})$$

- Higgs spin 0:** collinear leptons (low $m_{\ell\ell}$ and $\Delta\phi_{\ell\ell}$) \Rightarrow suppress WW background
- Production mechanism:** ggF (0 or 1 jet); VBF (≥ 2 jets; low bkg and low theory uncertainty)
 - ★ **VBF:** $|\Delta y_{jj}| > 2.8$; $m_{jj} > 500$ GeV
- Jet energy scale and resolution and b-tagging efficiency are the main sources of experimental systematic uncertainty

$H \rightarrow WW^* \rightarrow \ell\nu\ell\nu$ background

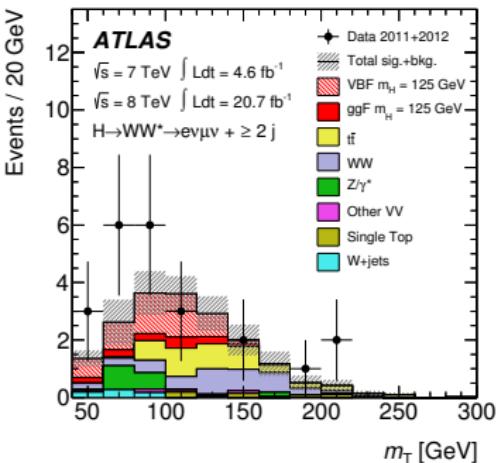

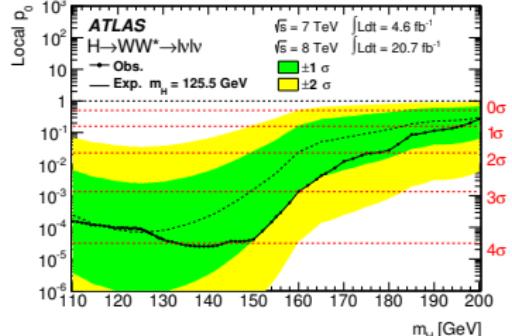

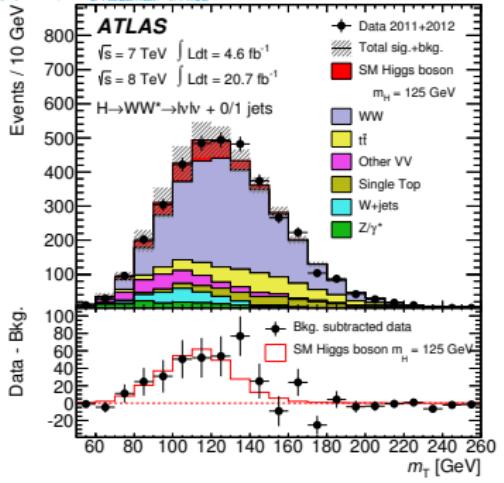

Background	Why fake signal?	criteria to reduce	normalized from
WW	large irreducible bkg	low $m_{\ell\ell}$	data
top ($t\bar{t}$ and single top)	lose a b-jet	b-jet veto	data
$W+\text{jets}$	jet fakes ℓ	tight iso & ℓ ID	data
$Z+\text{jets}$	fake/real E_T	$E_T + \text{low } m_{\ell\ell}$	data
other diboson	lost/misidentified ℓ	veto extra ℓ	MC

- WW CR, $N_{\text{jet}} \leq 1$ final states:
 - ★ $|\Delta\phi_{\ell\ell}|$ criteria is removed
 - ★ $m_{\ell\ell}$ bounds are modified

$H \rightarrow WW^* \rightarrow l\bar{v}l\bar{v}$ transverse mass

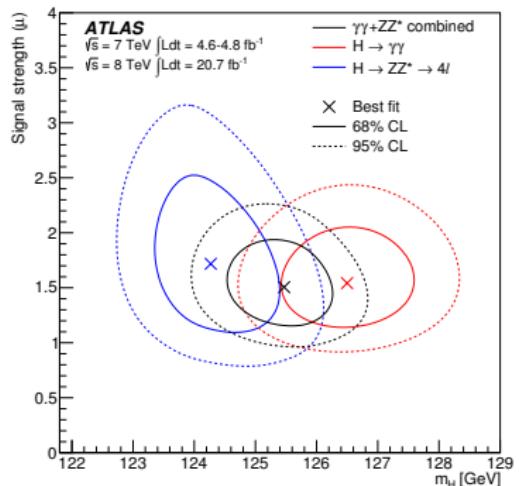

- excess of events observed in data
- VBF contributes 81% of the predicted signal in the $N_{jet} \geq 2$ final states
- maximum deviation (4.1σ) at $m_H = 140 \text{ GeV}$

Mass measurements and signal strengths

■ **signal strength:** $\mu = \sigma_{\text{observed}} / \sigma_{\text{SM}}$

■ μ largest deviation ($\sim 1.9\sigma$) observed in
 $H \rightarrow \gamma\gamma$

ATLAS

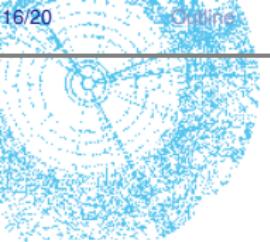

m_H = 125.5 GeV

	$\sigma(\text{stat})$	$\sigma(\text{sys})$	Total uncertainty	$\pm 1\sigma$ on μ
$H \rightarrow \gamma\gamma$	+0.23 -0.22	+0.24 -0.18	+0.24 -0.18	$\mu = 1.55^{+0.33}_{-0.28}$
$H \rightarrow ZZ^* \rightarrow 4l$	+0.35 -0.32	+0.20 -0.13	+0.35 -0.32	$\mu = 1.43^{+0.40}_{-0.35}$
$H \rightarrow WW^* \rightarrow l\bar{l}l\bar{l}$	+0.20 -0.21	+0.23 -0.19	+0.23 -0.19	$\mu = 0.99^{+0.31}_{-0.28}$
Combined $H \rightarrow \gamma\gamma, ZZ^*, WW^*$	+0.13 -0.14	+0.17 -0.13	+0.17 -0.13	$\mu = 1.33^{+0.21}_{-0.18}$

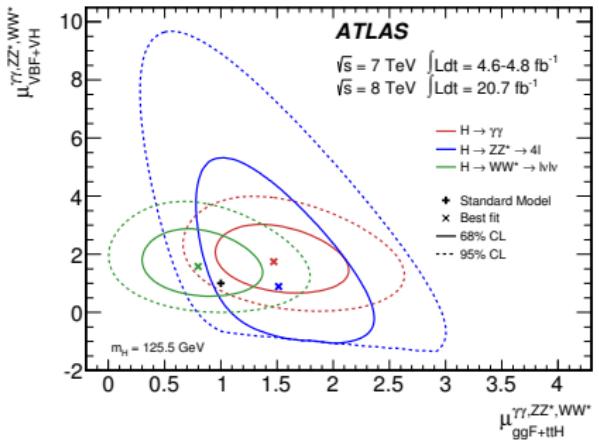

$\sqrt{s} = 7 \text{ TeV} \int L dt = 4.6\text{--}4.8 \text{ fb}^{-1}$
 $\sqrt{s} = 8 \text{ TeV} \int L dt = 20.7 \text{ fb}^{-1}$

Signal strength (μ) from 0.5 to 2.

Production mechanisms

ATLAS

$m_H = 125.5 \text{ GeV}$

H $\rightarrow \gamma\gamma$

$$\frac{\mu_{\text{VBF+VH}}}{\mu_{\text{ggF+ttH}}} = 1.1^{+0.9}_{-0.5}$$

H $\rightarrow ZZ^* \rightarrow 4l$

$$\frac{\mu_{\text{VBF+VH}}}{\mu_{\text{ggF+ttH}}} = 0.6^{+2.4}_{-0.9}$$

H $\rightarrow WW^* \rightarrow ll\nu\nu$

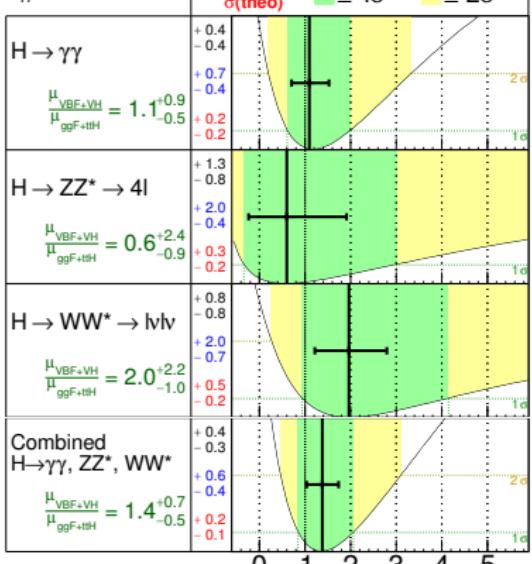

$$\frac{\mu_{\text{VBF+VH}}}{\mu_{\text{ggF+ttH}}} = 2.0^{+2.2}_{-1.0}$$

Combined
H $\rightarrow \gamma\gamma, ZZ^*, WW^*$

$$\frac{\mu_{\text{VBF+VH}}}{\mu_{\text{ggF+ttH}}} = 1.4^{+0.7}_{-0.5}$$

Total uncertainty

$\pm 1\sigma$ $\pm 2\sigma$

$\sqrt{s} = 7 \text{ TeV } \int L dt = 4.6\text{--}4.8 \text{ fb}^{-1}$

$\sqrt{s} = 8 \text{ TeV } \int L dt = 20.7 \text{ fb}^{-1}$

$\mu_{\text{VBF+VH}} / \mu_{\text{ggF+ttH}}$

Summary

- ❑ Data recorded by the ATLAS experiment in 2011/2012 allowed to test the fundamental properties of the discovered Higgs boson
- ❑ Significance of the observed mass peak is 7.4σ in $H \rightarrow \gamma\gamma$ and 6.6σ in $H \rightarrow ZZ \rightarrow 4\ell$ channel (discovery level in each of these channels)
- ❑ Mass of the Higgs boson measured to be $m = 126.8 \pm 0.2(\text{stat.}) \pm 0.7(\text{syst.})$ in $H \rightarrow \gamma\gamma$ and $m = 124.3^{+0.6}_{-0.5}(\text{stat.})^{+0.5}_{-0.3}(\text{syst.})$ in $H \rightarrow ZZ \rightarrow 4\ell$ (better than 9 per mil)
- ❑ All measurements are consistent with expectations for the SM Higgs boson

Backup Slides

Statistical method

- Construct a likelihood of Poisson probabilities, with expected numbers of events:

$$N^k = n_{\text{sig}}^k + n_{\text{bkg}}^k$$

- For the analysis k , signal scaling factors per each production i and decay f :

$$n_{\text{sig}}^k = \left(\sum_i \mu_i \times \sigma_{i,\text{SM}} \times A_{if}^k \times \epsilon_{if}^k \right) \times \mu_f \times BR_{f,\text{SM}} \times \mathcal{L}^k$$

cross section modifier: $\mu_i = \sigma_i / \sigma_{i,\text{SM}}$

branching ratio modifier: $\mu_f = BR_f / BR_{i,\text{SM}}$

- Test hypothesized values of parameter of interest μ with profiled likelihood ratio:

$$q_\mu = -2\Delta \ln \mathcal{L} = -2 \ln \frac{\mathcal{L}(\text{data}|\mu, \hat{\theta}_\mu)}{\mathcal{L}(\text{data}|\hat{\mu}, \hat{\theta})}$$

maximized likelihood for a fixed μ

μ and θ that maximize likelihood
