# TWISS FUNCTIONS 

## Lecture 4 <br> January 2014

## P.J. Bryant

## Introduction

## * So far we have:

* Derived the $\mathbf{2}^{\text {nd }}$ order differential equations of motion in 'hard-edge' field models for various elements,
$\%$ Obtained the corresponding equations of motion,
$\%$ Expressed the solutions in terms of $2 \times 2$ and $2 \times 3$ matrices,
* Used the matrices to track ions though a lattice using a local curvilinear co-ordinate system that follows the central orbit.

In this way, we have physical co-ordinates for individual ions that are easy to understand.

* An extension of the above approach is the use of the Twiss and Dispersion functions to describe envelopes as well as individual trajectories. This approach opens the way to other concepts such as emittance, aperture and acceptance.
* Twiss functions and dispersion functions are so widely used that they are needed to understand virtually all of the literature!

[^0]
## 'Twiss' functions

One of the historical mysteries in accelerators is how the 'Twiss' functions got their name. Twiss was once asked to elucidate this problem and he claimed there was no paper that made the link to him.

## There are two ways of looking at Twiss

 functions:The first is to regard them as a parametric way of expressing the motion equation and its solution. This interpretation makes the bridge from tracking single ions to the wider view of calculating beam envelopes.

The second is to regard them as purely geometric parameters for defining ellipses and hence beam envelopes. Dropping the strict correspondence to individual ions can lead to some interesting extensions such as the inclusion of scattering.

[^1]
## Twiss and the transverse motion equation

The general motion equation has the form,

$$
\frac{\mathrm{d}^{2} z}{\mathrm{~d} s^{2}}+K_{\mathrm{z}}(s) z=0
$$

where $z$ can be either $x$ or $y$.

* Start by parameterising the coordinate $z$ as,

$$
z(s)=A \beta_{z}(s)^{1 / 2} \cos \left[\int_{0}^{s} \frac{\mathrm{~d} \sigma}{\beta_{z}(\sigma)}+B\right] \quad \text { (2) }
$$

where $z(s)$ represents either of the transverse coordinates, $s$ is the distance along the equilibrium orbit, $A$ and $B$ are constants depending on the starting conditions, $\beta(s)$ is the betatron amplitude function and $\sigma$ is the integration variable representing distance.
The phase, $\mu(s)$ of the pseudo oscillation is given by,

$$
\begin{equation*}
\mu_{z}(s)=\int_{0}^{s} \frac{1}{\beta_{z}(\sigma)} \mathrm{d} \sigma \tag{3}
\end{equation*}
$$

[Of course, we do the above parameterisation with hindsight. Annals of Physics, vol. 3, p1-48 [1958] by E.D. Courant \& H.S. Snyder explains how to come to this point.]

## JUAS14_04- P.J. Bryant - Lecture 4

Twiss functions -

## Twiss \& transverse motion continued

To complete this description, the derivative of $\beta(s)$ is added to the set of relations,

$$
\begin{equation*}
\alpha_{z}(s)=-\frac{1}{2} \frac{\mathrm{~d} \beta_{z}}{\mathrm{~d} s} \tag{4}
\end{equation*}
$$

and

$$
\begin{equation*}
\gamma_{z}(s)=\frac{1+\alpha_{z}^{2}}{\beta_{z}} \tag{5}
\end{equation*}
$$

Note:
The phase shift for 1 turn in a ring divided by $2 \pi$ is known as the tune, $Q$ :

$$
\begin{equation*}
Q_{\mathrm{z}}=\frac{\mu_{z, 1 \text { Turn }}}{2 \pi}=\frac{1}{2 \pi} \oint_{\text {Circ. }} \frac{1}{\beta_{z}(\sigma)} \mathrm{d} \sigma \tag{6}
\end{equation*}
$$

$\alpha, \beta$ and $\gamma$ are distinguished from the relativistic parameters by a suffix for the plane, but this later dropped for brevity.
Equations (1) to (5) are so widely used that they need to be committed to memory.

[^2]
## More Twiss

Substitution of (2) into (1) yields a differential equation for $\sqrt{ } \beta_{z}(s)$ that is more complicated than the original motion equation, which at first sight seems a poor deal,

$$
\begin{equation*}
\frac{\mathrm{d}^{2} \sqrt{\beta_{z}}}{\mathrm{~d} s^{2}}+K_{z}(s) \sqrt{\beta_{z}}=\left(\sqrt{\beta_{z}}\right)^{-3} \tag{7}
\end{equation*}
$$

(To derive this you will need the $\alpha_{z}$ function.)

* Equation (7) is rarely used, but it is necessary to know it exists.
Today, we will take the approach of comparing the matrix equations to the equivalent Twiss equations. This leads to a whole battery of equations, but they appear so often that they eventually become familiar.

[^3]
## General Twiss transfer matrix

Re-express equation (2) as,

$$
z(s)=A \beta^{1 / 2} \cos \mu+B \beta^{1 / 2} \sin \mu
$$

where $A$ and $B$ are different constants and the suffix ' $z$ ' has been dropped for brevity.
Differentiation gives,
$z^{\prime}(s)=-A \beta^{-1 / 2}(\alpha \cos \mu+\sin \mu)+B \beta^{-1 / 2}(\cos \mu-\alpha \sin \mu)$
The constants $\boldsymbol{A}$ and $\boldsymbol{B}$ can be replaced using the initial conditions at $s=s_{1}$,

$$
A=z_{1} \beta_{1}^{-1 / 2} \quad \text { and } \quad B=z_{1}^{\prime} \beta_{1}^{1 / 2}+z_{1} \alpha_{1} \beta_{1}^{-1 / 2}
$$

To get the general transfer matrix from position $s_{1}$ to position $s_{2}$, write the phase advance from $s_{1}$ to $s_{2}$ as $\Delta \mu$, so that,

$$
\left.\begin{array}{l}
\boldsymbol{M}\left(s_{1} \rightarrow s_{2}\right)= \\
\left(\frac{\beta_{2}}{\beta_{1}}\right)^{1 / 2}\left(\cos \Delta \mu+\alpha_{1} \sin \Delta \mu\right) \\
-\left(\beta_{1} \beta_{2}\right)^{-1 / 2}\left[\left(1+\alpha_{1} \alpha_{2}\right) \sin \Delta \mu+\left(\alpha_{2}-\alpha_{1}\right) \cos \Delta \mu\right] \tag{8}
\end{array}\right)
$$

JUAS14_04- P.J. Bryant - Lecture 4
Twiss functions -

# Twiss transfer matrix for a single turn in a ring or for a matched cell 

When equation (8) is applied to a full turn in a ring or to matched cell, the input conditions equal the output conditions (i.e. $\alpha=\alpha_{1}=\alpha_{2}, \beta=\beta_{1}=\beta_{2}$, $\Delta \mu=2 \pi Q)$, so that,

$$
\left(\begin{array}{lc}
\boldsymbol{M}_{1 \text { turn }}= \\
\left(\begin{array}{cc}
\cos 2 \pi Q+\alpha \sin 2 \pi Q) & \beta \sin 2 \pi Q \\
-\gamma \sin 2 \pi Q & (\cos 2 \pi Q-\alpha \sin 2 \pi Q)
\end{array}\right) \tag{9}
\end{array}\right.
$$

Remember $Q$ is known as the tune and is the number of betatron oscillations around a ring. We will see in the next section that equation (9) allows us to unambiguously solve for $\alpha, \beta$ and $\gamma$ in terms of the matrix coefficients, at least for a ring. We will treat transfer lines much later because they require some further thought.

[^4]
## Solving Twiss in a ring

A lattice program can proceed as follows: List all the elements in the lattice
Calculate the transfer matrix of all elements. Multiply all the matrices to obtain the singleturn matrix.
Compare this matrix to equation (8) and solve for $\alpha, \beta$ and $\gamma$ using,

$$
\begin{align*}
\sin 2 \pi Q & =\frac{m_{12}}{\left|m_{12}\right|} \sqrt{1-\left(\frac{m_{11}+m_{22}}{2}\right)^{2}}  \tag{10}\\
\beta & =\frac{m_{12}}{\sin 2 \pi Q}  \tag{11}\\
\alpha & =\frac{\left(m_{11}-m_{22}\right)}{2 \sin 2 \pi Q} \tag{12}
\end{align*}
$$

To step round the lattice, pre-multiply by the matrix of the next element after the observation point and post multiply by the inverse of the same matrix.
$M\left(s_{n} \rightarrow s_{n-1}\right)=M_{n}{ }^{-1} M\left(s_{1} \rightarrow s_{n}\right) M_{n}$

## Solving for $Q$ and $\mu$

Let $Q=2 n \pi+q$, where $n$ is an integer.
Equation (10) allows you to solve for $\sin (2 \pi Q)$.

* $\operatorname{Tan}(2 \pi Q)$ or $\cos (2 \pi Q)$ can also be found easily.

This allows you to find $q$ (the fractional part), but NOT $n$ (the integer part).

To find the integer number of oscillations around a ring, or the total phase shift through a long line, it is necessary to step through the lattice with steps less than $2 \pi$ and to sum up for the total.

This can be done in a number of ways but, with the information given so far, use the previous slide to find $\alpha, \beta$ and $\gamma$ at all elements in the ring and then use equation (8) to cross each element to find the $\Delta \mu$ values.

The dispersion function $(D)$ and the derivative of the dispersion function ( $\mathrm{d} D / \mathrm{d} s$ ) are usually listed and included graphically with the Twiss parameters to give a complete description of the beam.

JUAS14_04- P.J. Bryant - Lecture 4
Twiss functions -

## Dispersion

To complete the parameterisation of the particle motion we need to include the motion of offmomentum ions using,

$$
z(s)=\underbrace{A \beta(s)^{1 / 2} \cos \left[\int_{0}^{s} \frac{\mathrm{~d} \sigma}{\beta(\sigma)}+B\right]}_{\text {Betatron motion }}+\underbrace{D(s) \frac{\Delta p}{p} \quad(13)}_{\text {Dispersion motion }}
$$

$D(s)$ is known as the dispersion function.
An analytic derivation of the dispersion function is possible, but it is usual to rely on lattice programs for numerical listings of $D(s)$ and its derivative with distance $D^{\prime}(s)$.

* The dispersion function is found in much the same way as was done for $\alpha$ and $\beta$.
* For rings, the cyclic condition is imposed,

$$
\left(\begin{array}{c}
D\left(s_{0}\right) \\
D^{\prime}\left(s_{0}\right) \\
1
\end{array}\right)=\left(\begin{array}{ccc}
m_{11} & m_{12} & m_{13} \\
m_{21} & m_{22} & m_{23} \\
0 & 0 & 1
\end{array}\right)_{1 \text { Turn }}\left(\begin{array}{c}
D\left(s_{0}\right) \\
D^{\prime}\left(s_{0}\right) \\
1
\end{array}\right)
$$

where the matrix is for one turn and the input and output values of $D(s)$ and $D^{\prime}(s)$ are equated.

[^6]
## Dispersion continued

* The dispersion and its derivative at the point of evaluation of the matrix can be solved as,

$$
\begin{aligned}
& D\left(s_{0}\right)=\frac{\left(1-m_{22}\right) m_{13}+m_{12} m_{23}}{\left(2-m_{11}-m_{22}\right)} \\
& D^{\prime}\left(s_{0}\right)=\frac{\left(1-m_{11}\right) m_{23}+m_{21} m_{13}}{\left(2-m_{11}-m_{22}\right)}
\end{aligned}
$$

* Having found the dispersion vector at one point, $s_{0}$, it is simple to tabulate the values at all intermediate points in the ring by either stepping the single-turn matrix round as was already described, or by tracking the vector through the structure from the known point, $s_{0}$, to a new point, $s_{1}$, by,

$$
\left(\begin{array}{c}
D\left(s_{2}\right) \\
D^{\prime}\left(s_{2}\right) \\
1
\end{array}\right)=\left(\begin{array}{ccc}
t_{11} & t_{12} & t_{13} \\
t_{21} & t_{22} & t_{23} \\
0 & 0 & 1
\end{array}\right)_{s_{0}-s_{1}}\left(\begin{array}{c}
D\left(s_{0}\right) \\
D^{\prime}\left(s_{0}\right) \\
1
\end{array}\right)
$$

JUAS14_04- P.J. Bryant - Lecture 4
Twiss functions -

## Phase space

Returning to equation (2) substituted with (3),

$$
z(s)=A \beta^{1 / 2} \cos (\mu+B)
$$

Differentiating gives,

$$
z^{\prime}(s)=-A \alpha \beta^{-1 / 2} \cos (\mu+B)-A \beta^{-1 / 2} \sin (\mu+B)
$$

* If these two equations are used to plot a graph for $\left(z, z^{\prime}\right)$ for $\mu=0$ to $2 \pi$, one gets an ellipse.

In the case of a ring or matched cell, the periodicity imposes equality on the input and output $\alpha$ and $\beta$ values. This means that the particle returns after each turn or transit to the same ellipse but at phases $\mu_{1}=B$, $\mu_{2}=B+2 \pi Q, \mu_{3}=B+2 \pi Q, \ldots . ., B+n 2 \pi Q$ and so on.

## Motion invariant

The elimination of the phase advance from (14) and (15) yields an invariant of the motion,

$$
\begin{equation*}
A^{2}=\gamma^{2}+2 \alpha z z^{\prime}+\beta z^{\prime 2} \tag{16}
\end{equation*}
$$

This is known as the Courant \& Snyder Invariant.
The motion invariant, $A^{2}$, equals the (area $/ \pi$ ) of the ellipse described by the betatron motion in phase space. When referring to a single ion, this area is sometimes called the single-particle emittance, although this is strictly incorrect (see slide on emittance).

All ions in the beam will have a value for this invariant (area/ $\pi$ ) and follow similar ellipses.

JUAS14_04- P.J. Bryant - Lecture 4 Twiss functions -

## Liouville's theorem

## Liouville states that phase space is conserved.

Primarily, this refers to 6-dimensional phase space ( $x-x^{\prime}, y-y^{\prime}$ and $s-\mathrm{d} p / p$ ). You will have more detailed descriptions in later lectures defining conjugate variables etc.

* When the component phase spaces are uncoupled, the phase space is conserved within the $\mathbf{2}$-dimensional and/or 4-dimensional spaces.

The invariant of the motion in the uncoupled $x-x^{\prime}$ or $y-y^{\prime}$ spaces is another way of saying the phase space is conserved.

Phase space is not conserved if ions change, e.g. by stripping or nuclear fragmentation, or if non-Hamiltonian forces appear e.g. scattering or photon emission.

## Transferring Twiss functions

We have calculated the Twiss functions from the single-turn matrix of a ring and shown how to step round the ring to make a table of the functions.
We have shown that the Twiss functions define an ellipse in phase space and the area of this ellipse is a constant of the motion.
Thus, between two points,

$$
\begin{align*}
A^{2} & =\gamma_{2} z_{2}^{2}+2 \alpha_{2} z_{2} z_{2}^{\prime}+\beta_{2} z_{2}^{\prime 2} \\
& =\gamma_{1} z_{1}^{2}+2 \alpha_{1} z_{1} z_{1}^{\prime}+\beta_{1} z_{1}^{\prime 2} \tag{17}
\end{align*}
$$

[Note this trick of equating the invariant at 2 points.] A trajectory at the two points is related by the transfer matrix $T\left(s_{1} \rightarrow s_{2}\right)$, which on this occasion is more conveniently written in the inverse form from points 2 to 1, as,

$$
\binom{z}{z^{\prime}}_{1}=\left(\begin{array}{cc}
t_{22} & -t_{12} \\
-t_{21} & t_{11}
\end{array}\right)\binom{z}{z^{\prime}}_{2} \quad(18)
$$

[Note that the modulus is unity so that the inverse is simplified. Remember this for questions.]

## JUAS14_04- P.J. Bryant - Lecture 4

# Transferring Twiss functions continued 

Equation (18) can be used to substitute for $\left(z_{1}, z_{1}^{\prime}\right)$ on the right hand side of (17). After regrouping the terms, expressions for $\alpha_{2}, \beta_{2}$ and $\gamma_{2}$ can be found in terms of $\alpha_{1}, \beta_{1}$ and $\gamma_{1}$. These results are usually written in the form of a $3 \times 3$ matrix,

$$
\left(\begin{array}{l}
\beta \\
\alpha \\
\gamma
\end{array}\right)_{2}=\left(\begin{array}{ccc}
t_{11}^{2} & -2 t_{11} t_{12} & t_{12}^{2} \\
-t_{11} t_{21} & {\left[t_{11} t_{22}+t_{12} t_{21}\right]} & -t_{12} t_{22} \\
t_{21}^{2} & -2 t_{21} t_{22} & t_{22}^{2}
\end{array}\right)\left(\begin{array}{l}
\beta \\
\alpha \\
\gamma
\end{array}\right)_{1}
$$

Special case. In a drift space, $t_{11}=t_{22}=1, t_{12}=\ell$ and $t_{21}=0$, so that,

$$
\beta_{2}=\beta_{1}-2 \ell \alpha_{1}+\ell^{2} \gamma_{1}
$$

[Note this is often used in questions.]

## Emittance

* The emittance of a beam is related to the phase-space area that it occupies and is therefore related to the motion invariants of the constituent ions (see previous slide).

A practical definition of emittance requires a choice for the limiting ellipse that defines the phase-space area of the beam. Usually this is related to some number of standard deviations of the beam distribution, but it could also be the overall ellipse that includes all ions or some fraction of the ions. The definition is best included in the name e.g. 'the $\mathbf{9 5 \%}$ emittance equals...' or 'the 1 -sigma emittance is...'.

* A further problem of definition is whether the emittance is the phase-space area or the phase-space area divided by $\pi$. Since the literature mixes these two definitions, it is better to express the emittance with the $\pi$ apparent, i.e. $30 \pi \times 10^{-6}[\mathrm{~m} \mathrm{rad}]$ or $30 \times 10^{-6}[\pi \mathrm{~m}$ rad] . In this way, the user sees that the $\pi$ is included, but can easily remove it if desired.

## In this paper:

Geometric emittance, $\varepsilon=$ Phase-space area
$\pi$ will be apparent in numerical values and definitions AND we write geometric emittance to distinguish it from the normalised emittance that comes later.

JUAS14_04- P.J. Bryant - Lecture 4 Twiss functions -

## Beam envelopes and Acceptance

Referring back to equation (14),

$$
z(s)=A \beta^{1 / 2}(s) \cos (\mu(s)+B)
$$

The amplitude of the oscillation of an ion is given by,

$$
w(s)=A \beta^{1 / 2}(s)
$$

* If we talk of a beam, then the envelope or beam width is given by,

$$
\begin{equation*}
w(s)=\sqrt{\frac{\beta(s) \varepsilon}{\pi}} \tag{21}
\end{equation*}
$$

where $\varepsilon$ is the emittance. This is a useful formula. The beam envelope or width is subject to the same definitions problems as the emittance. So, for example, the beam envelope calculated with the 1 sigma emittance will be the 1 -sigma envelope, the beam envelope calculated with the $\mathbf{9 5 \%}$ emittance will be the $95 \%$ beam envelope and so on.
The area (or area $/ \pi$ ) of the largest phase-space ellipse that can pass through a lattice is know as the acceptance. This is a description of the lattice and not the beam.

In the horizontal plane, the inner pair of lines define the dispersion width and the outer lines the betatron width. In the vertical plane, the dispersion is zero and only the betatron width is visible.

JUAS14_04- P.J. Bryant - Lecture 4

## Geometry of the phase-space ellipse

Practical emittance definition that defines ellipse:

$$
\varepsilon=\pi\left(\gamma_{\mathrm{y}} z^{2}{ }_{1-\sigma}+2 \alpha_{\mathrm{y}} z_{1-\sigma} z_{1-\sigma}^{\prime}+\beta_{\mathrm{y}} z^{\prime 2}{ }_{1-\sigma}\right)
$$

JUAS14_04- P.J. Bryant - Lecture 4
Twiss functions -

## Transfer lines

It was mentioned earlier that transfer lines were in some way different to rings.

The lack of periodicity in a transfer line removes the constraint that the Twiss functions at the exit must equal those at the entry and consequently the Twiss functions are undefined unless the user supplies the values at some reference point, e.g. at the exit from a ring (where the functions are known) which is the entry to the transfer line.

Understanding this difference and the implications can take some time, so be patient.

[^7]
## Transfer lines continued

A single ion in phase space provides insufficient information to associate it with one unique set of Twiss functions (see Figure). Without additional information, a single point can be equally well represesented by any of an infinite number of sets of Twiss functions (i.e. families of ellipses). Once an arbitrary choice has been made for the Twiss functions, a unique emittance can always be found that places the single ion on just one ellipse in that family. This arbitrary set of parameters can then be tracked through the lattice and will always represent the ion's motion correctly.

JUAS14_04- P.J. Bryant - Lecture 4

## Transfer lines continued

A collection of ions in phase space will, subject to interpretation, define a unique set of Twiss parameters and an emittance that together define the beam.

One can always impose a statistical solution on the phrase 'subject to interpretation' by making a least squares fit of an ellipse to the ion distribution.

JUAS14_04- P.J. Bryant - Lecture 4

## What happens when a transfer line <br> meets a ring?

* In transfer lines, the ellipse always "belongs" to the beam, or at least the user's interpretation of what the beam should be. If one were to be strict, one should mark the Twiss parameters in some way to show this, but this is rarely done.
* In a ring, the matched ellipse "belongs" to the lattice because it is defined by the periodicity.
* If now a beam ellipse, that is not equal to the matched ellipse, is injected into a ring and observed at the same position in the ring over several turns, it will turn with regular angular steps inside the matched ellipse (see Figure).

In this situation, the beam has a mismatched ellipse and the ring is effectively behaving like a long transfer line that has a repeating structure.

## Debunching and filamentation

* After a few thousand turns the structure of the mismatched ellipse will start to be lost and the beam will fill the matched ellipse. The matched ellipse corresponds to the Twiss parameters as derived earlier for a ring. These parameters "belong" to the lattice and always impose themselves on any beam that circulates in the ring for a large number of turns.
* Two processes spread out the ions in the mismatched ellipse to fill the matched ellipse.
- A momentum spread, however small, introduces a spread in the revolution frequency that destroys the initial distribution. This is a chromatic or debunching effect.
* There is always some non-linearity that correlates tune value with amplitude. This effect, called filamentation, distorts the initial ellipse into an " $S$ " shape (see Figure). As the tails grow longer they grow narrower. From the mathematician's viewpoint, phase-space area is always conserved (Liouville's theorem), but for all practical purposes filamentation is a loss of phase-space density and an increase in emittance.

## Chromaticity

Chromaticity refers to effects caused by a momentum dependence. The name arises because the momentum of an ion is closely analogous to the frequency, and hence the colour, of light in classical optics.

* The dispersion function that arises from the differential bending in dipoles for ions of different momenta is strictly a chromaticity effect, but it is not referred to as such.
* The effect arising from the differential focusing with momentum causes the betatron phase advance or tune in a ring to change with momentum. This is generally known as the chromaticity and can be defined in two ways:

$$
\begin{equation*}
Q^{\prime}=\frac{\Delta Q}{\Delta p / p} \quad \text { or } \quad \zeta=\frac{\Delta Q / Q}{\Delta p / p} \tag{22}
\end{equation*}
$$

The first definition is the more widely used, but the second definition is liked for its symmetry.
The next level of chromaticity is the variation of $\alpha$ and $\beta$ with momentum. This is treated by formulating a socalled $w$-vector, which is too advanced to be tackled here.

## Summary

* We have parameterised the motion equation and obtained what are known as the Twiss and Dispersion functions.
* The Twiss functions define ellipses in phase space that correspond to the invariant of the motion for single ions and the emittance for beams.
* We looked at rings first and found that the Twiss functions are uniquely defined and 'belong' to the lattice.
* We found how to calculate the Twiss functions around a ring.
* We then went back and considered transfer lines and found that the Twiss functions are not uniquely defined and it is necessary for the designer to define values at one point (that he can choose).
* Twiss values in transfer lines 'belong' to the beam.
- Debunching and filamentation were discussed.
* Finally, we defined chromaticity.
