## WHY TO STUDY JETS?

At LHC jet production is the dominant high  $p_T$  process.

Jet cross sections give us precise informations about the structure of the proton.

They are a powerful tool for understanding the strong interaction and searching for physics beyond Standard Model.

# THE EXPERIMENT

2010 data sample

The goal of this experiment is the measurement of the inclusive jet and dijet **cross sections**:

$$\text{Cross-section } \sigma = \frac{N_{\text{signal}} - N_{\text{background}}}{\epsilon \mathcal{L}}$$

INCLUSIVE JET: measurement of the cross sections of all the jets of the event.

DIJET: measurement of the cross section of only the two highest  $p_{\text{T}}$  jets.

The **luminosity** is  $(37.3 \pm 1.2) \text{ pb}^{-1}$  (2000 times larger than that of the previous study): a new kinematic region is explored!

There are many theoretical predictions: next-to-leading order (NLO) QCD calculations corrected for non perturbative effects and NLO Monte Carlo predictions.

# THE ATLAS CALORIMETER

- ECAL with LAr (endcap, barrel, forward)
- HCAL (barrel, extended barrel, endcap, Fcal)

The total calorimeter covers the region  $|\eta| < 4.9$ .

# TRIGGER

Three different triggers are used in this measurement:

1. MBTS (Minimum Bias Trigger Scintillators), in front of endcap cryostats, selects events with jets in the range  $20 < p_T < 60$  GeV.

They are composed of three consecutive levels: L1, L2 and Event Filter (EF).

2. Central trigger  
3. Forward trigger

The triggers act independently using several thresholds for the transverse energy of the jet  $E_t \equiv E \sin \theta$ .

For each L1 threshold there is a corresponding L2 threshold of about 15 GeV higher.

## CROSS SECTION DEFINITION

Jets are reconstructed using *anti- $k_T$  algorithm*, where clustering starts from the most energetic objects, with  $r=0.4$  and  $r=0.6$ :

$$r = \sqrt{(\Delta y)^2 + (\Delta \phi)^2}$$

*Inclusive jet* double-differential cross sections are measured as a function of jet  $p_T$  in bins of  $y$ , in the region  $p_T > 20 \text{ GeV}$ ,  $|y| < 4.4$ .

*Dijet* double-differential cross sections are measured as a function of invariant mass of the two leading jets:

$$m_{12} = \sqrt{(E_1 + E_2)^2 - (\vec{p}_1 + \vec{p}_2)^2}$$

Dijet cross sections are binned in the variable  $y^*$  that is the rapidity in the two-parton centre of mass frame:

$$y^* = \frac{1}{2} \ln \left( \frac{1 + |\cos \theta^*|}{1 - |\cos \theta^*|} \right)$$

# OFFLINE SELECTION

1. Event Selection → Avoid background, cosmic rays...
  - At least one primary vertex consistent with the beams.
  - At least five tracks associated with the vertex.

## 2. Jet Selection

- Inclusive Jets:  $p_T > 20$  GeV and  $|y| < 4.4$ .
- Dijets: one with  $p_T > 20$  GeV and the other one with  $p_T > 30$  GeV .
- Efficiency measured using a Tag & Probe method.
  - ✓ Greater than 99% for  $p_T > 60$  GeV.

} Efficiency over 99%

# EXPERIMENTAL UNCERTAINTIES

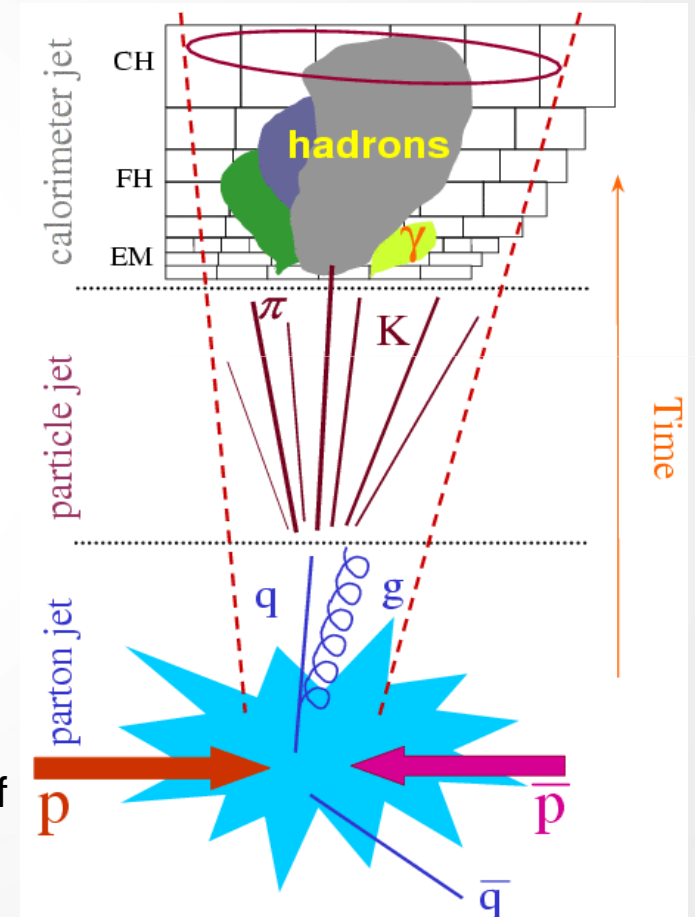

- › Non-collision background is taken to be negligible.
- › The uncertainty from mis-modeling of the vertex position is taken to be negligible.
- › Pile-up is negligible.
- › The uncertainty on the luminosity is 3.4%.
- › The biggest contribution to uncertainty comes from the Jet Energy Scale (JES).

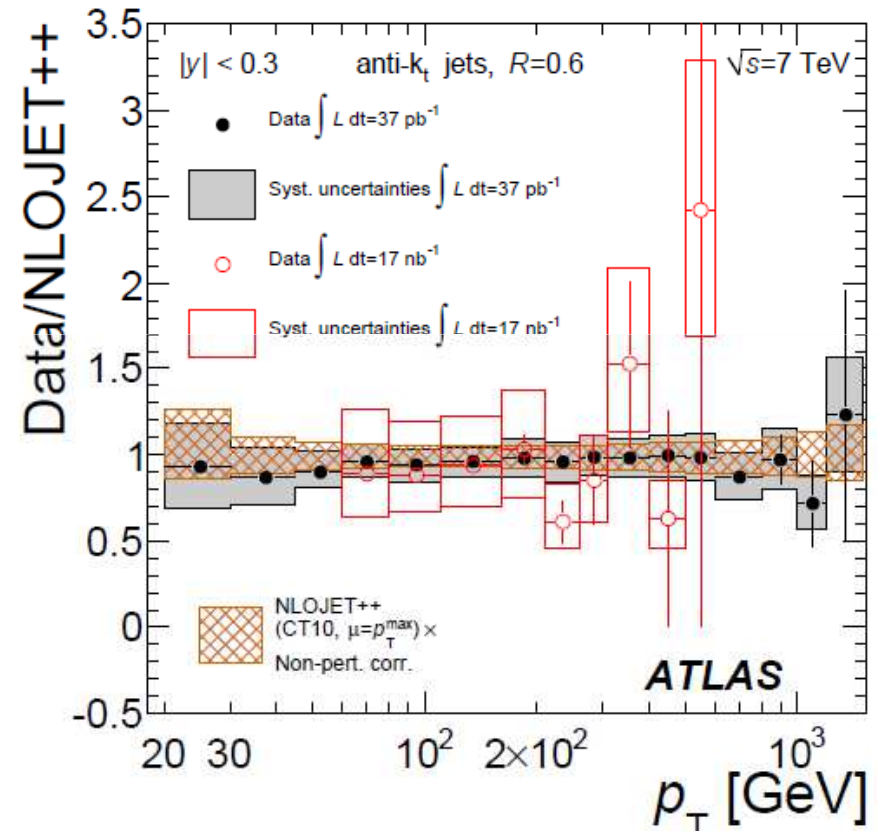

# COMPARING THEORY AND EXPERIMENT

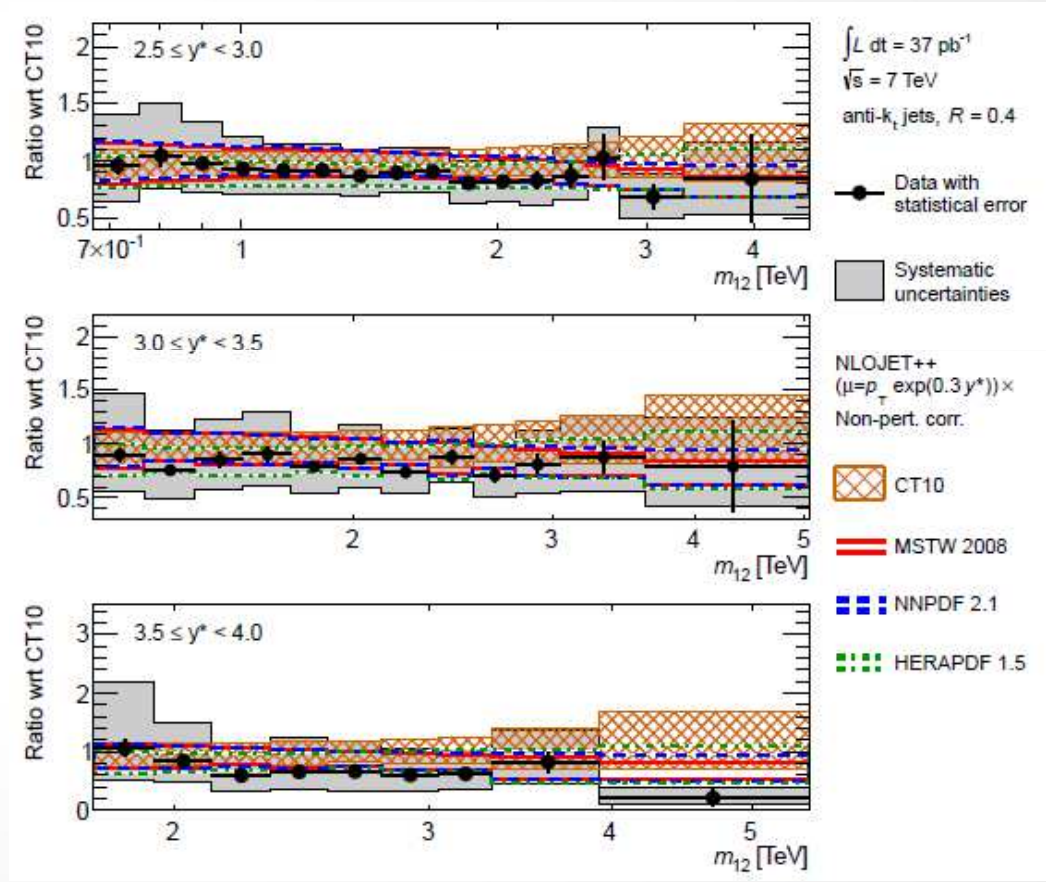

- Experiment: from energy depositions to particle jet.
  - Using a Montecarlo simulation a correction for the detector effects can be derived. This is done using an *unfolding* method.
- Theory: from parton to particle jet.
  - The hadronization can be switched on and off in the Montecarlo simulation. Comparing both samples the Non-Pertubative Corrections are derived.
- The Montecarlo simulation was cross-checked comparing the shapes of the resulting jets.

# RESULTS: INCLUSIVE JET CROSS SECTIONS

# RESULTS: DIJET CROSS SECTIONS

## CONCLUSIONS

- Cross section measurements for inclusive jets and dijets reconstructed with two different clustering parameters have been presented and compared.
  - The measurements have been corrected to particle level.
  - These results probe NLO pQCD in a new kinematic regime.
  - The cross sections are compared with NLO pQCD calculations. In spite of the good agreement, predicted cross sections tend to be larger at high energy.
  - These measurements probe unexplored areas of parton distribution functions at large  $x$  and large momentum transfer.
- ✓ **These results constitute a comprehensive test of QCD across a large kinematic regime.**

**THE END**

*Thanks for your attention!*
