

# Astroparticle physics news

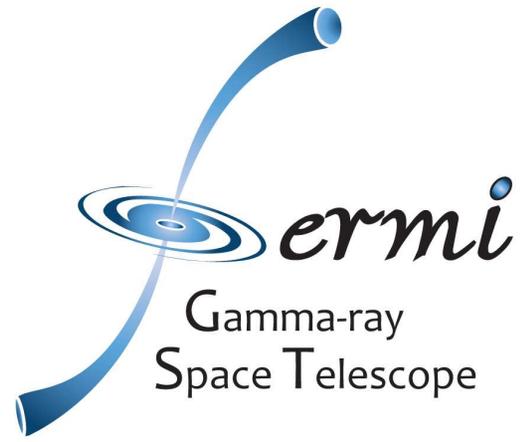

- The mystery of distant blazars  $\Rightarrow$  secondary gamma rays and PeV neutrinos
- IceCube neutrinos: astrophysical or dark matter?
- X-ray line at 3.5 keV? If it's real, what it implies.

(...more or less, in the order from “astro” to “particle”.)

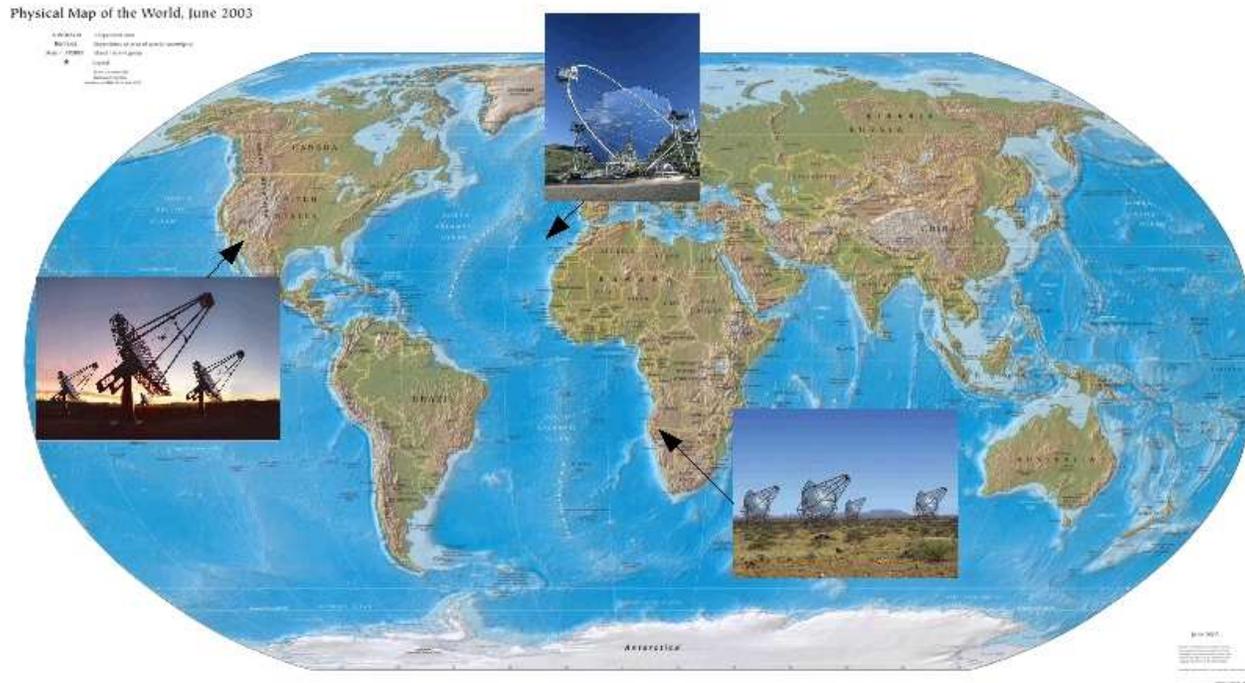

## Active galactic nuclei: blazars

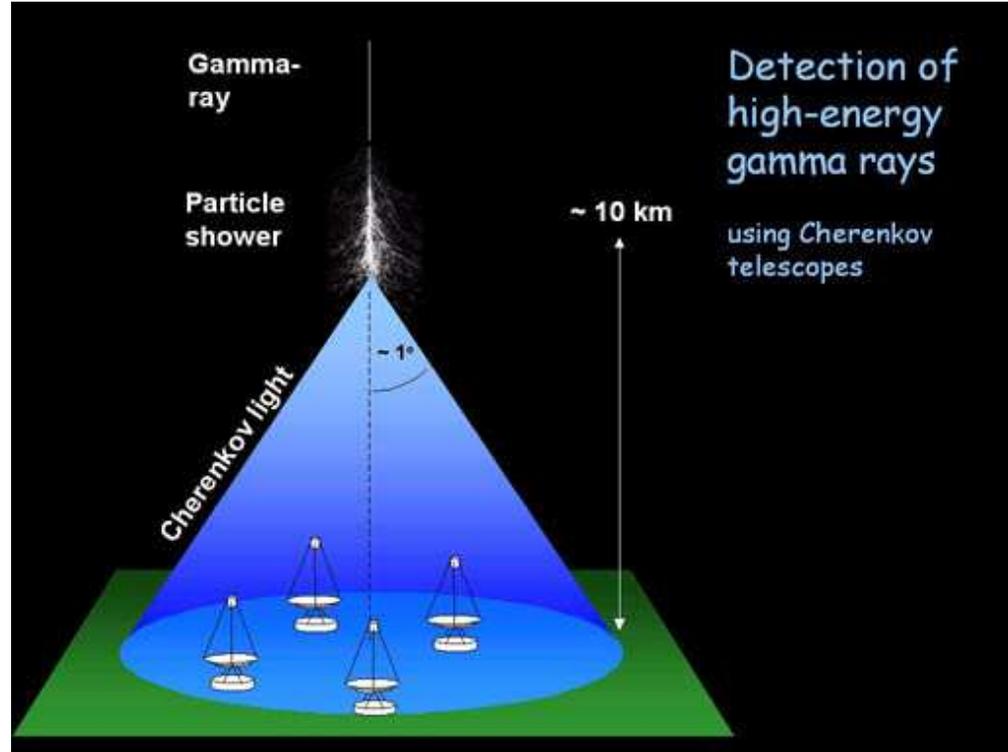

when AGN jet points at Earth, called *blazar*

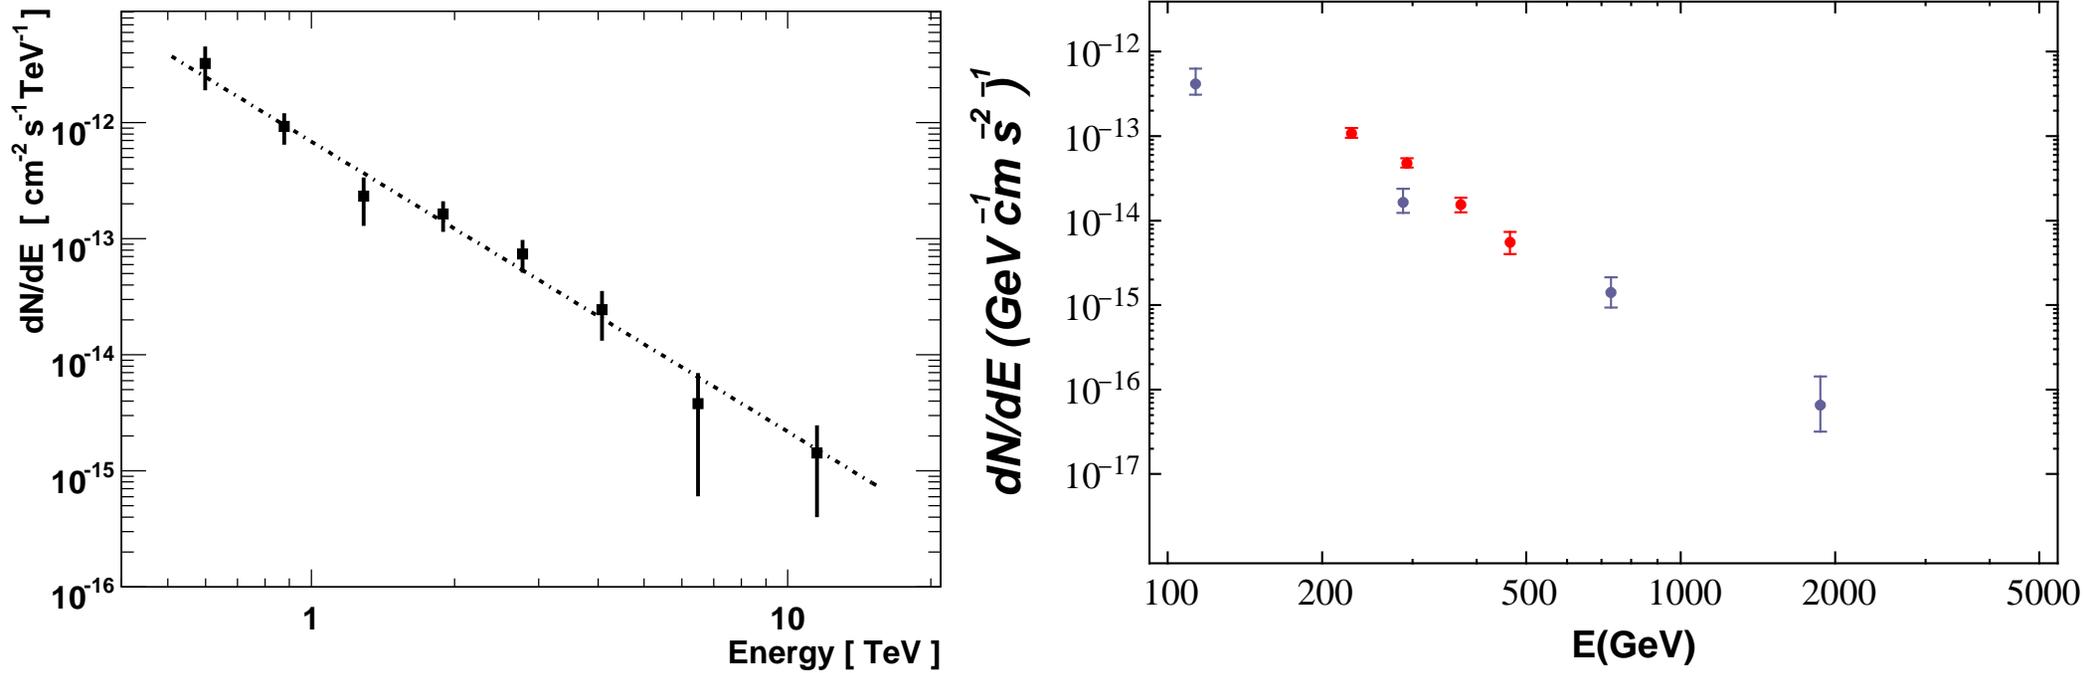

# Atmospheric Cherenkov Telescopes

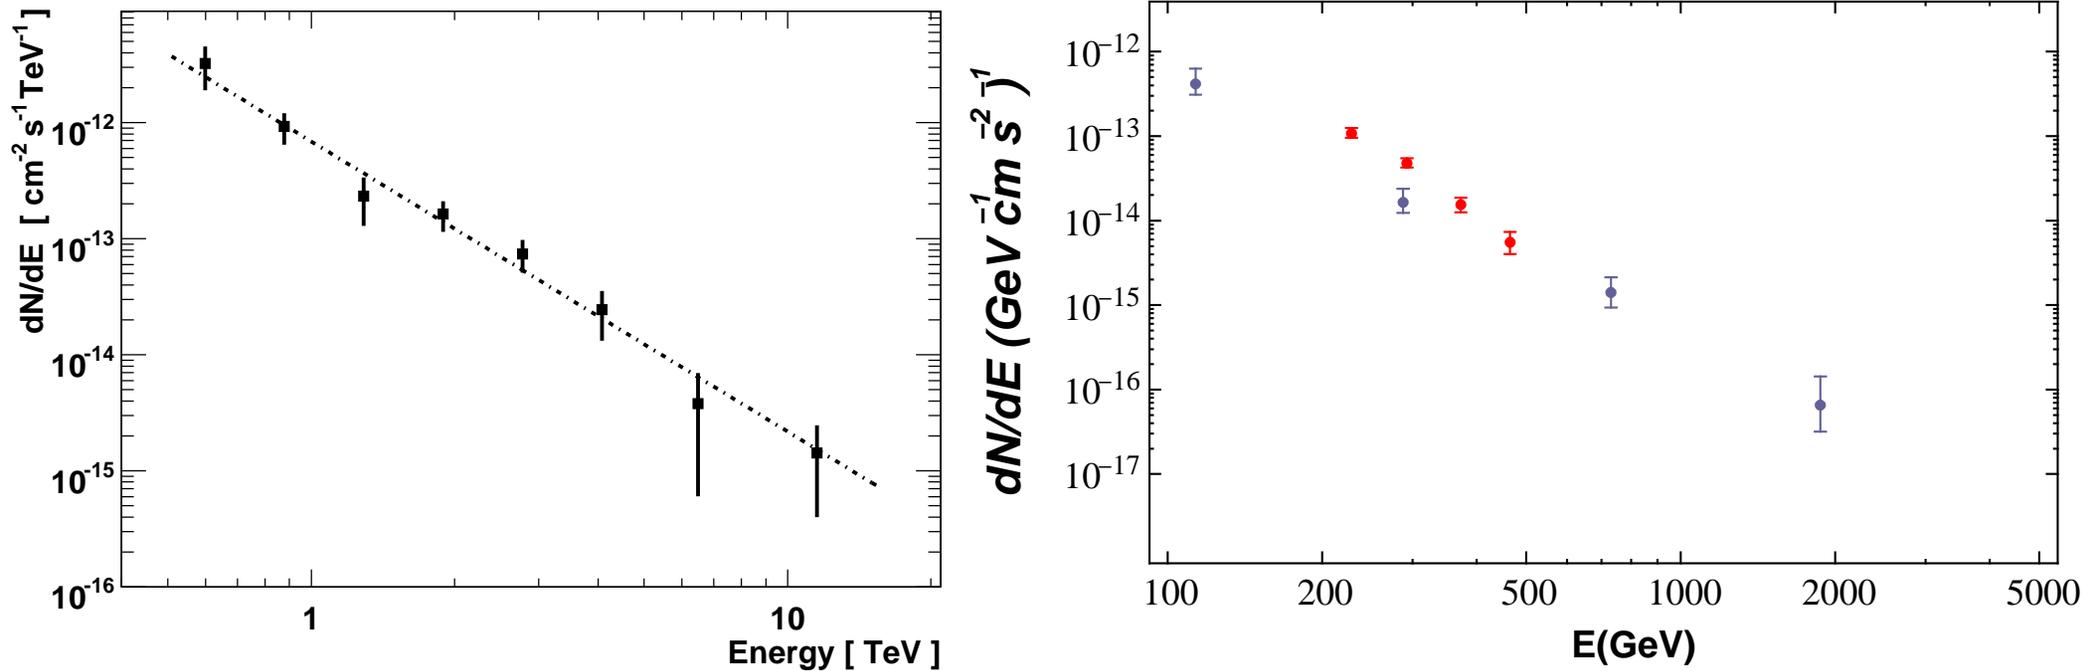

## Gamma-ray observations of distant blazars: 1ES 0229+200 ( $z = 0.14$ ) and 3C66A ( $z = 0.44$ )

HESS (black), MAGIC (blue) and VERITAS (red) data points

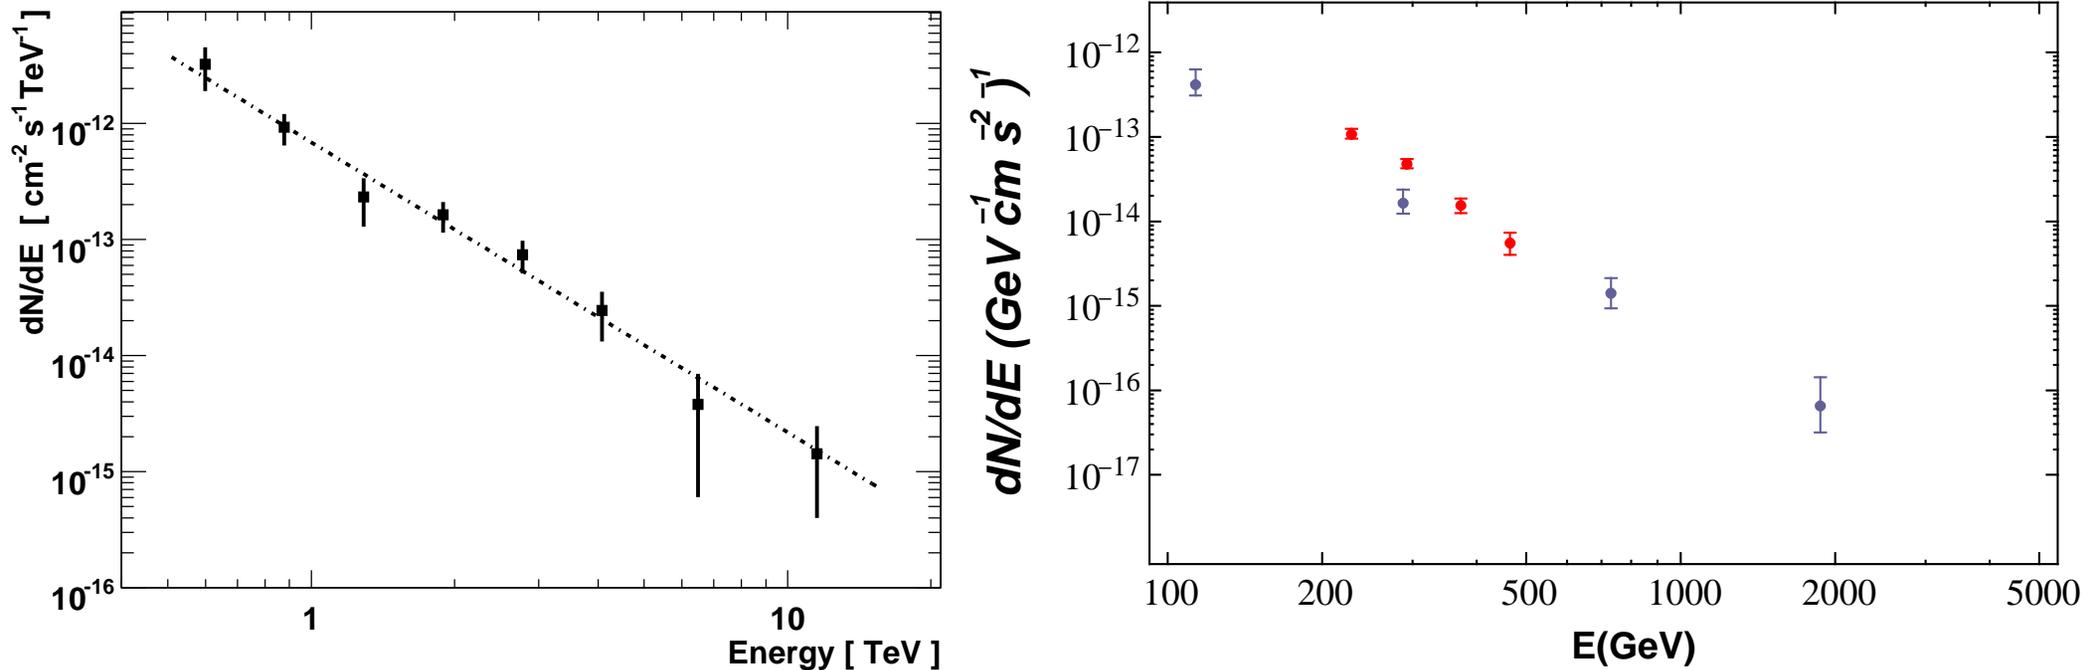

## Gamma-ray observations of distant blazars: 1ES 0229+200 ( $z = 0.14$ ) and 3C66A ( $z = 0.44$ )

HESS (black), MAGIC (blue) and VERITAS (red) data points

Theory, e.g., Stecker, et al. (1992): ...“we predict a sharp cutoff between 0.1 and 1 TeV”

## Gamma-ray observations of distant blazars: 1ES 0229+200 ( $z = 0.14$ ) and 3C66A ( $z = 0.44$ )

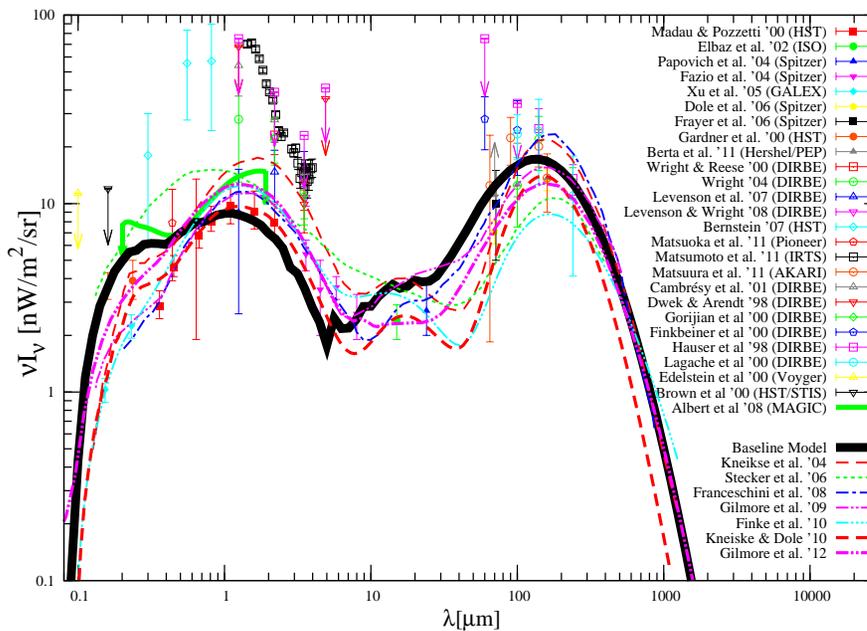

HESS (black), MAGIC (blue) and VERITAS (red) data points

Theory, e.g., Stecker, et al. (1992): ...“we predict a sharp cutoff between 0.1 and 1 TeV”

**The data:** no signs of absorption due to  $\gamma\gamma_{EBL} \rightarrow e^+e^-$

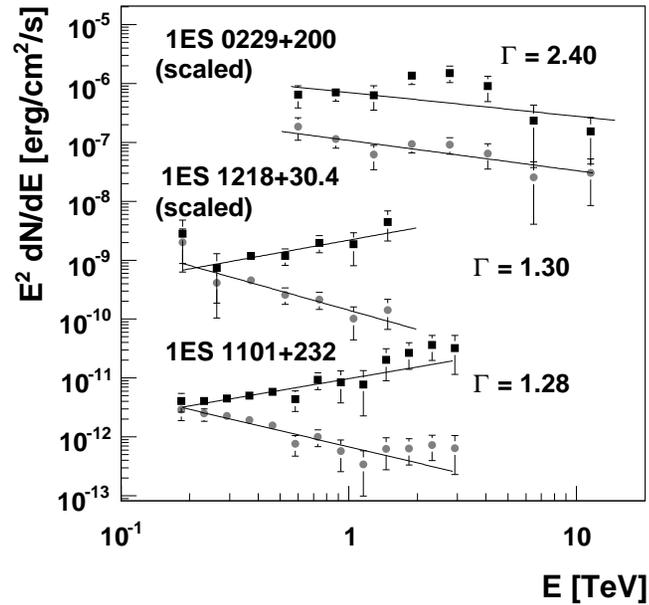

## Extragalactic background light (EBL) (direct and processed starlight)

- intimately connected with star formation history and with dust content of the galaxies
- models uncertain, but *robust lower limits* exist from star counts, especially for UV EBL

$\gamma\gamma_{EBL} \rightarrow e^+e^-$  should degrade  
the energy of TeV photons

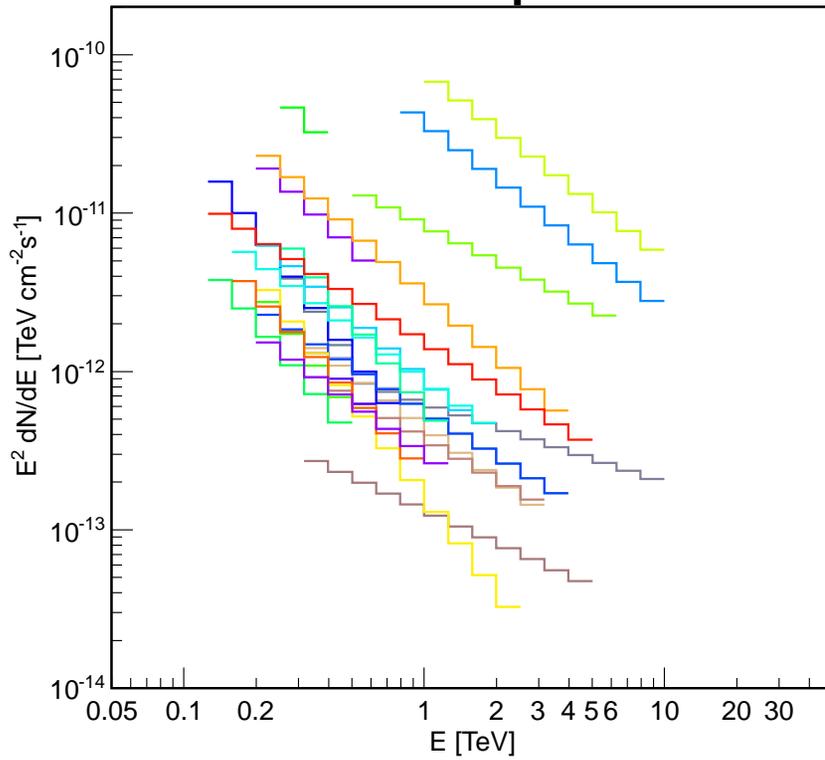

**Distant blazars have implausibly hard spectra**

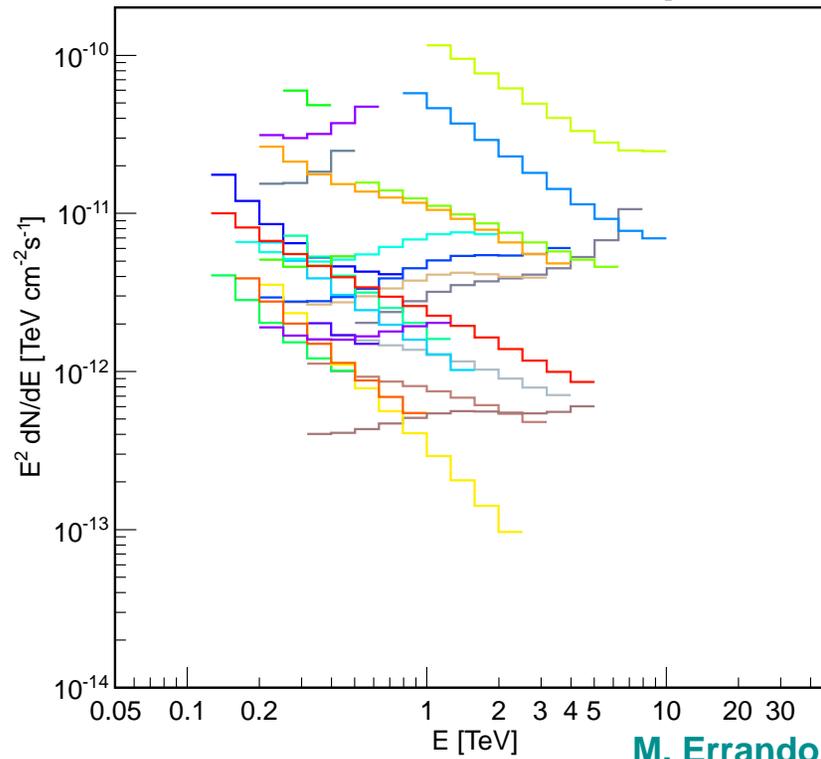

**Absorption-corrected spectra are extremely hard,  $\Gamma < 1.5$ , for distant blazars.** [Aharonian et al.]

M. Errando

## Softening of the spectrum as a function of the redshift

$$\Delta\Gamma = \Gamma_{\text{GeV}} - \Gamma_{\text{TeV}} \quad \text{[Stecker, Scully]}$$

### Distant blazars are different:

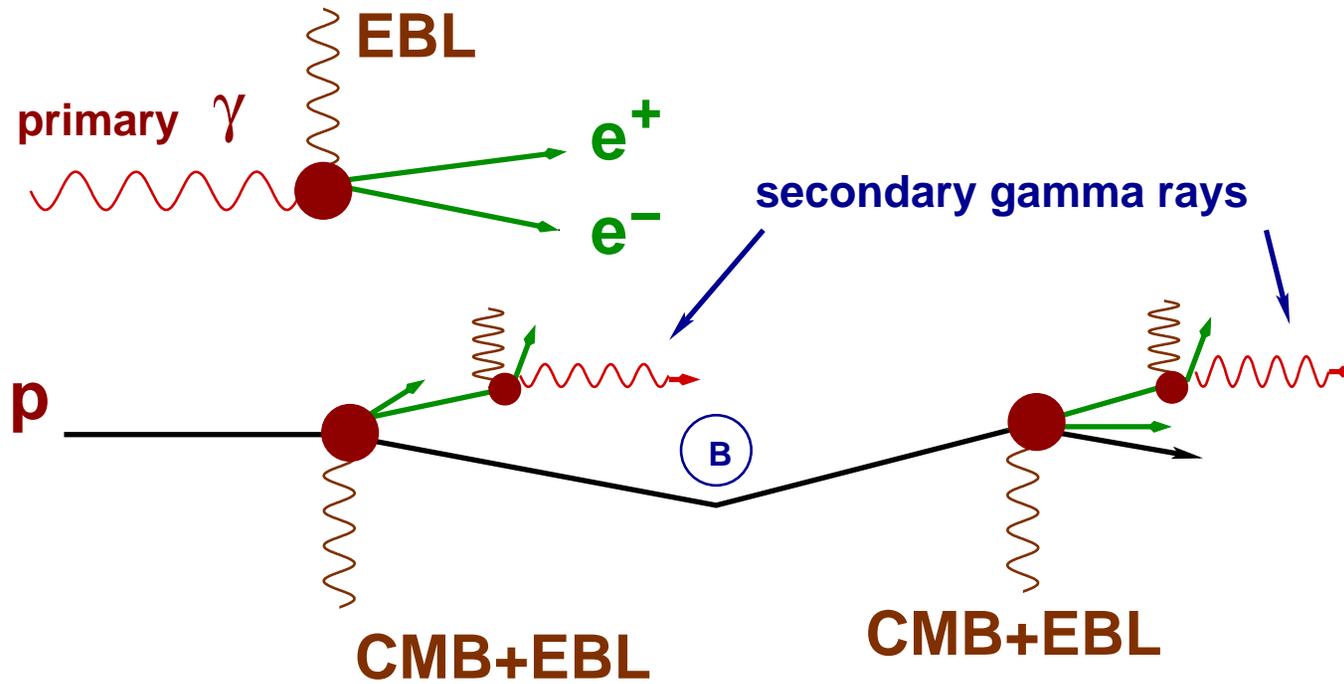

## Proposed “new physics” solutions:

The lack of absorption prompted some exotic solutions:

- photons may convert into some hypothetical *axion-like particles* that convert back into photons in the galactic magnetic fields  
[Hooper et al.; de Angelis et al.; Simet et al.]
- *Lorentz invariance violation* for high-velocity particles may prevent pair production  
[Protheroe et al.]

Is there a more conventional explanation?

# AGN produce both cosmic rays and gamma rays

## Cosmic rays from AGN

- **No significant attenuation** below GZK cutoff.  
Propagate cosmological distances for  $E \lesssim 10^{18}$  eV.
- **Rectilinear propagation** affected only by IGMFs.  
Clusters of galaxies (size  $R$ , density  $n$ ) cause large deflections, but the mean free path of a proton

$$\Lambda \sim 1/(\pi R^2 n) \sim 3 \times 10^3 \text{ Mpc}$$

The mean MFP for linear propagation is of the order of the size of the observed universe.

- **IGMFs are not known:**
  - upper limits:  $B < 10^{-9}$  G from non-observation of Faraday rotations
  - lower limits:  $B > 10^{-30}$  G if one believes the galactic fields are seed fields amplified by dynamo.

For magnetic fields  $B < 10^{-14}$  G, deflections are smaller than the angular resolution of ACTs.

## Secondary gamma rays from cosmic rays along the line of sight?

Gamma-rays produced at the source can attenuate via pair production on EBL for TeV energies: expect **attenuation of TeV  $\gamma$  rays**.

Protons below GZK cutoff interact with EBL, CMB and produce  $\gamma$  rays via  $p\gamma \rightarrow pe^+e^-$ ,  $p\gamma \rightarrow p\pi^0$ : expect **regeneration of TeV  $\gamma$  rays**  
Photon backgrounds provide opacity/sink for the former, source for the latter.

What is the scaling of these effects with distance?

**Different scaling**

$$F_{\text{primary},\gamma}(d) \propto \frac{1}{d^2} \exp\{-d/\lambda_\gamma\} \quad (1)$$

$$F_{\text{secondary},\gamma}(d) = \frac{p\lambda_\gamma}{4\pi d^2} [1 - e^{-d/\lambda_\gamma}] \propto \begin{cases} 1/d, & \text{for } d \ll \lambda_\gamma, \\ 1/d^2, & \text{for } d \gg \lambda_\gamma. \end{cases} \quad (2)$$

$$F_{\text{secondary},\nu}(d) \propto (F_{\text{protons}} \times d) \propto \frac{1}{d}. \quad (3)$$

**Different scaling**

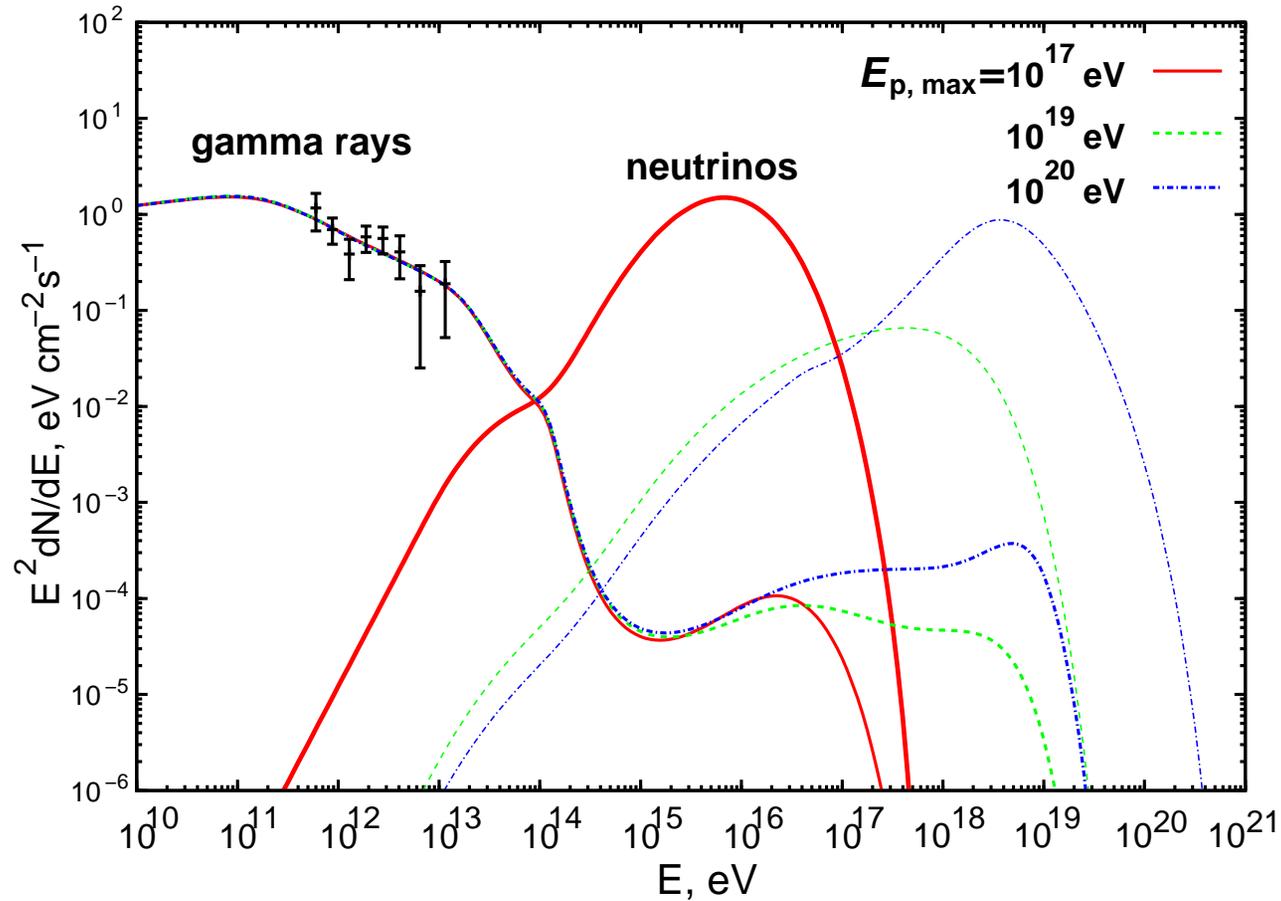

$$F_{\text{primary},\gamma}(d) \propto \frac{1}{d^2} \exp\{-d/\lambda_\gamma\} \quad (1)$$

$$F_{\text{secondary},\gamma}(d) = \frac{p\lambda_\gamma}{4\pi d^2} [1 - e^{-d/\lambda_\gamma}] \propto \begin{cases} 1/d, & \text{for } d \ll \lambda_\gamma, \\ 1/d^2, & \text{for } d \gg \lambda_\gamma. \end{cases} \quad (2)$$

$$F_{\text{secondary},\nu}(d) \propto (F_{\text{protons}} \times d) \propto \frac{1}{d}. \quad (3)$$

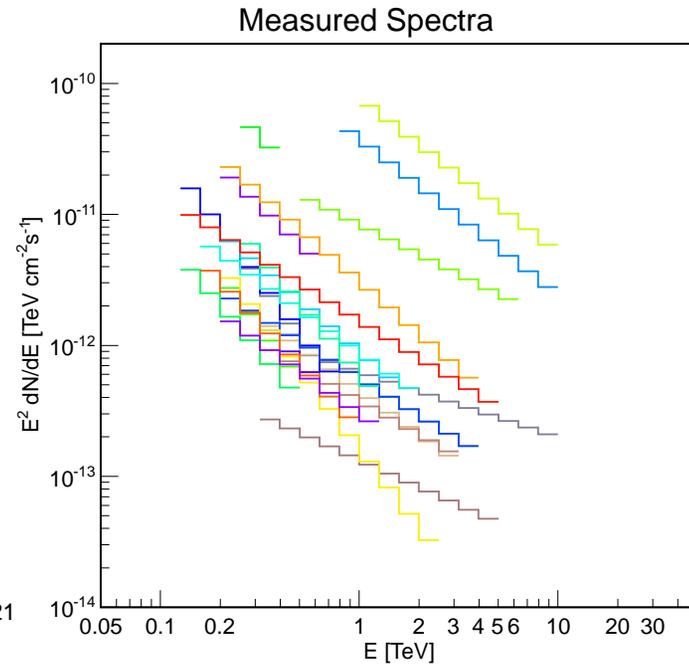

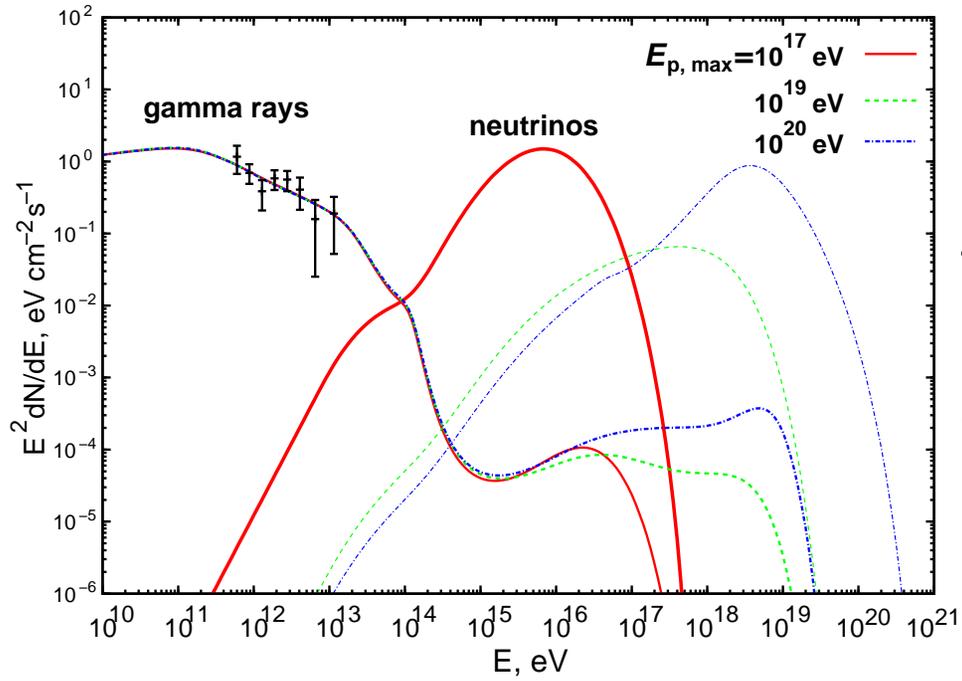

**For distant sources, secondary signals win**

# Secondary photons and neutrinos from 1ES0229+200 ( $z = 0.14$ )

## Can the IceCube neutrinos come from decays of heavy dark matter?

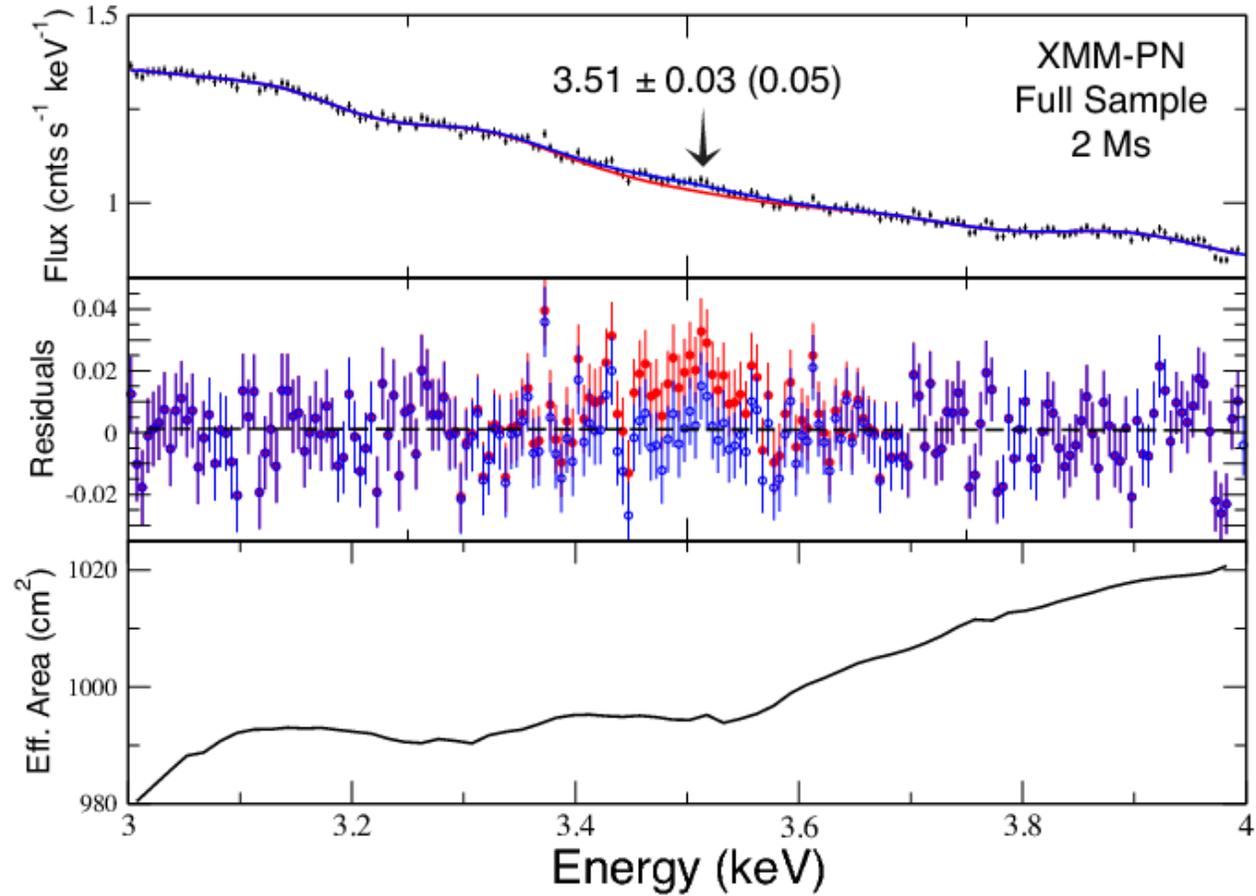

Possible types of DM particles: gravitino with R-parity violation; hidden sector gauge boson; a singlet fermion in an extra dimension; a heavy right-handed neutrino.

[Feldstein, AK, Matsumoto, Yanagida (2013)]

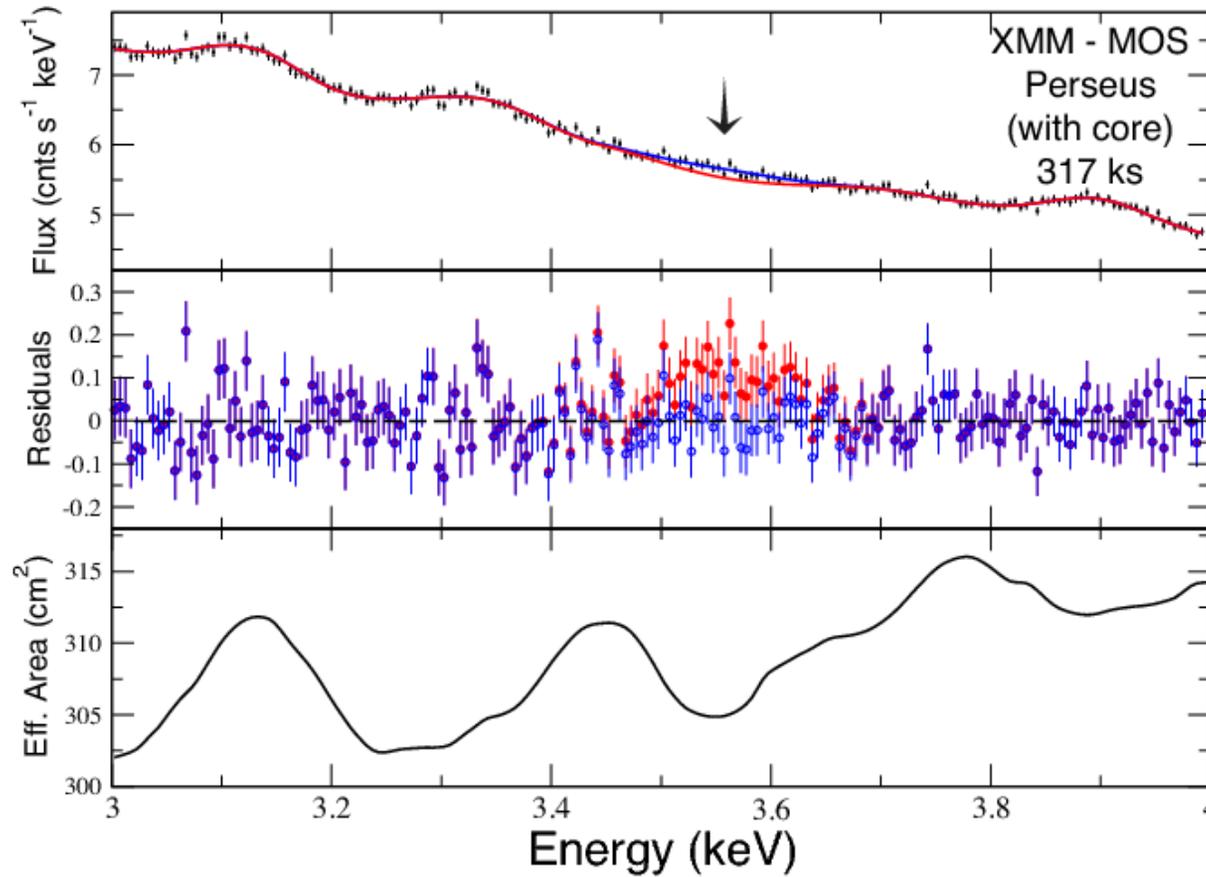

## Sterile neutrinos, moduli, and dark matter with a keV mass.

- Dark matter candidates at a keV scale: sterile neutrinos, string/supersymmetry moduli
- Warm or cold, depending on the production scenario
- Particle physics models
  - – Sterile neutrinos and an SU(2) singlet Higgs boson
  - – Sterile neutrinos and the Split Seesaw
  - – String/supersymmetry moduli
- Detection strategy: the search for a keV line

## Unidentified line from Bulbul et al.; Boyarsky et al.

## Unidentified line from Bulbul et al.; Boyarsky et al.

## Neutrino masses and light sterile neutrinos

Discovery of the neutrino masses implies a plausible existence of right-handed (sterile) neutrinos. Most models of neutrino masses introduce sterile states

$$\{\nu_e, \nu_\mu, \nu_\tau, \nu_{s,1}, \nu_{s,2}, \dots, \nu_{s,N}\}$$

and consider the following Lagrangian:

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \bar{\nu}_{s,a} (i\partial_\mu \gamma^\mu) \nu_{s,a} - y_{\alpha a} H \bar{L}_\alpha \nu_{s,a} - \frac{M_{ab}}{2} \bar{\nu}_{s,a}^c \nu_{s,b} + h.c.,$$

where  $H$  is the Higgs boson and  $L_\alpha$  ( $\alpha = e, \mu, \tau$ ) are the lepton doublets. The mass matrix:

$$M = \begin{pmatrix} 0 & D_{3 \times N} \\ D_{N \times 3}^T & M_{N \times N} \end{pmatrix}$$

What is the *natural* scale of  $M$ ?

## Seesaw mechanism

In the Standard Model, the matrix  $D$  arises from the Higgs mechanism:

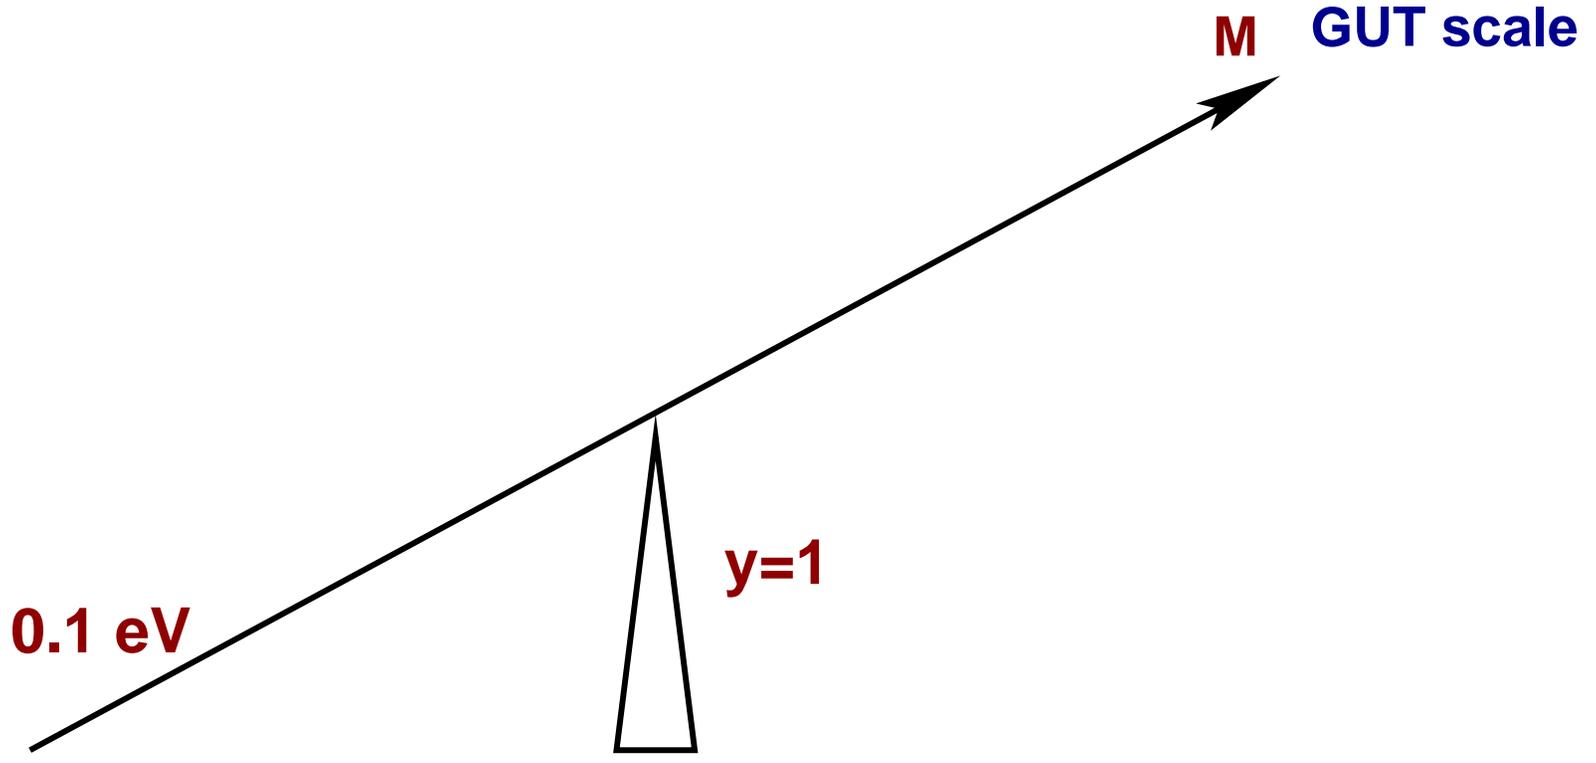

$$D_{ij} = y_{ij} \langle H \rangle$$

Smallness of neutrino masses **does not** imply the smallness of Yukawa couplings. For large  $M$ ,

$$m_\nu \sim \frac{y^2 \langle H \rangle^2}{M}$$

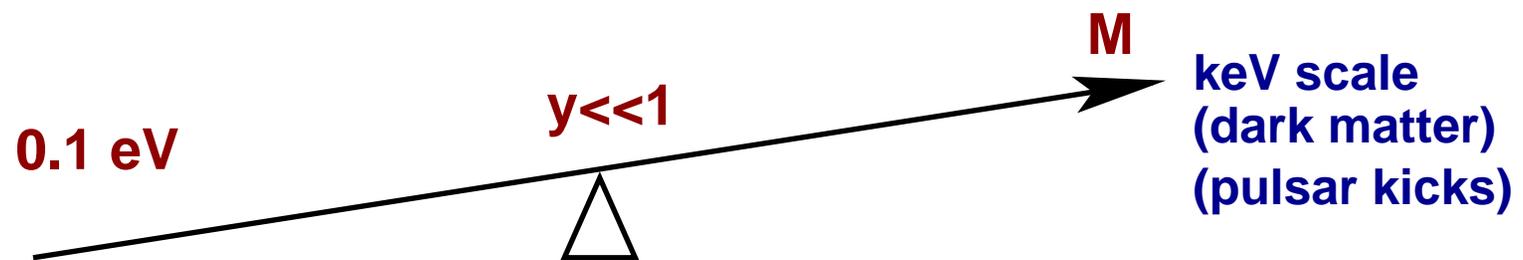

One can understand the smallness of neutrino masses even if the Yukawa couplings are  $y \sim 1$  [Gell-Mann, Ramond, Slansky; Yanagida; Glashow; Mohapatra, Senjanović].

**Seesaw mechanism**

**Seesaw mechanism**

**GUT scale**

## Various approaches to small Majorana masses

- Just write them down.
  - One sterile keV sterile neutrino, the dark matter candidate [Dodelson, Widrow].
  - Three sterile neutrinos, one with a several keV mass (dark matter) and two degenerate with GeV masses and a keV splitting,  $\nu$ MSM [Shaposhnikov et al.].
- Use **lepton number** conservation as the reason for a small mass [de Gouvêa].
- Use **flavor symmetries**, new gauge symmetries [Lindner et al.]
- **Singlet Higgs** (discussed below) at the electroweak scale can generate the Majorana mass. Added bonuses:
  - production from  $S \rightarrow NN$  at the electroweak scale generates *the right amount* of dark matter.
  - production from  $S \rightarrow NN$  at the electroweak scale generates *colder* dark matter.
 A “**miracle**”: EW scale and mass at the keV scale (for stability)  
 $\Rightarrow$  **correct DM abundance**. [AK; AK, Petraki]
- **Split seesaw** (discussed below) makes the scale separation natural. Dark matter cooled by various effects.  $\Rightarrow$  **democracy of scales**

## Sterile neutrinos as dark matter: production scenarios

Production color coded by “warmness” vs “coldness”:

## Sterile neutrinos as dark matter: production scenarios

Production color coded by “warmness” vs “coldness”:

- **Neutrino oscillations off resonance** [Dodelson, Widrow] No prerequisites; production determined by the mixing angle alone; no way to turn off this channel, except for low-reheat scenarios [Gelmini et al.]

## Sterile neutrinos as dark matter: production scenarios

Production color coded by “warmness” vs “coldness”:

- **Neutrino oscillations off resonance** [Dodelson, Widrow] No prerequisites; production determined by the mixing angle alone; no way to turn off this channel, except for low-reheat scenarios [Gelmini et al.]
- **MSW resonance in  $\nu_\alpha \rightarrow \nu_s$  oscillations** [Shi, Fuller] Pre-requisite: sizable lepton asymmetry of the universe. The latter may be generated by the decay of heavier sterile neutrinos [Laine, Shaposhnikov]

## Sterile neutrinos as dark matter: production scenarios

Production color coded by “warmness” vs “coldness”:

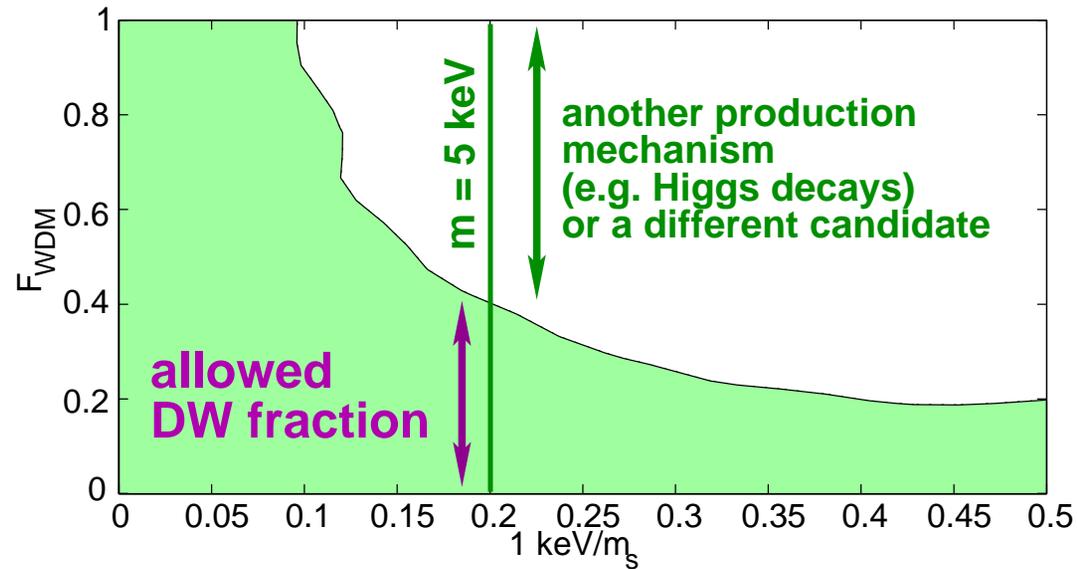

- **Neutrino oscillations off resonance** [Dodelson, Widrow] No prerequisites; production determined by the mixing angle alone; no way to turn off this channel, except for low-reheat scenarios [Gelmini et al.]
- **MSW resonance in  $\nu_\alpha \rightarrow \nu_s$  oscillations** [Shi, Fuller] Pre-requisite: sizable lepton asymmetry of the universe. The latter may be generated by the decay of heavier sterile neutrinos [Laine, Shaposhnikov]
- **Higgs decays** [AK, Petraki] Assumes the Majorana mass is due to Higgs mechanism. **Sterile miracle: abundance a “natural” consequence of singlet at the electroweak scale.** Advantage: “natural” dark matter abundance

## Sterile neutrinos as dark matter: production scenarios

Production color coded by “warmness” vs “coldness”:

- **Neutrino oscillations off resonance** [Dodelson, Widrow] No prerequisites; production determined by the mixing angle alone; no way to turn off this channel, except for low-reheat scenarios [Gelmini et al.]
- **MSW resonance in  $\nu_\alpha \rightarrow \nu_s$  oscillations** [Shi, Fuller] Pre-requisite: sizable lepton asymmetry of the universe. The latter may be generated by the decay of heavier sterile neutrinos [Laine, Shaposhnikov]
- **Higgs decays** [AK, Petraki] Assumes the Majorana mass is due to Higgs mechanism. **Sterile miracle: abundance a “natural” consequence of singlet at the electroweak scale.** Advantage: “natural” dark matter abundance
- **Split seesaw:** [AK, Takahashi, Yanagida]  
Two production mechanisms, **cold** and **even colder**.  
Advantage: “naturally” low mass scale

# Lyman- $\alpha$ bounds on Dodelson-Widrow production

[Boyarsky, Lesgourgues, Ruchayskiy, Viel]  
Free-streaming properties: [Boyanovsky; Petraki]

## New scale or new Higgs physics?

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \bar{N}_a (i\partial_\mu \gamma^\mu) N_a - y_{\alpha a} H \bar{L}_\alpha N_a - \frac{M_a}{2} \bar{N}_a^c N_a + h.c. ,$$

To explain the pulsar kicks and dark matter, one needs  $M \sim \text{keV}$ . Is this a new fundamental scale? Perhaps. Alternatively, it could arise from the Higgs mechanism:

$$\mathcal{L} = \mathcal{L}_{\text{SM}} + \bar{N}_a (i\partial_\mu \gamma^\mu) N_a - y_{\alpha a} H \bar{L}_\alpha N_a - h_a S \bar{N}_a^c N_a + V(H, S)$$

$$M = h \langle S \rangle$$

Now  $S \rightarrow NN$  decays can produce sterile neutrinos.

For small  $h$ , the sterile neutrinos are out of equilibrium in the early universe, but  $S$  is in equilibrium. There is a new mechanism to produce sterile dark matter at  $T \sim m_S$  from decays  $S \rightarrow NN$ :

$$\Omega_s = 0.2 \left( \frac{33}{\xi} \right) \left( \frac{h}{1.4 \times 10^{-8}} \right)^3 \left( \frac{\langle S \rangle}{\tilde{m}_S} \right)$$

Here  $\xi$  is the dilution factor due to the change in effective numbers of degrees of freedom.

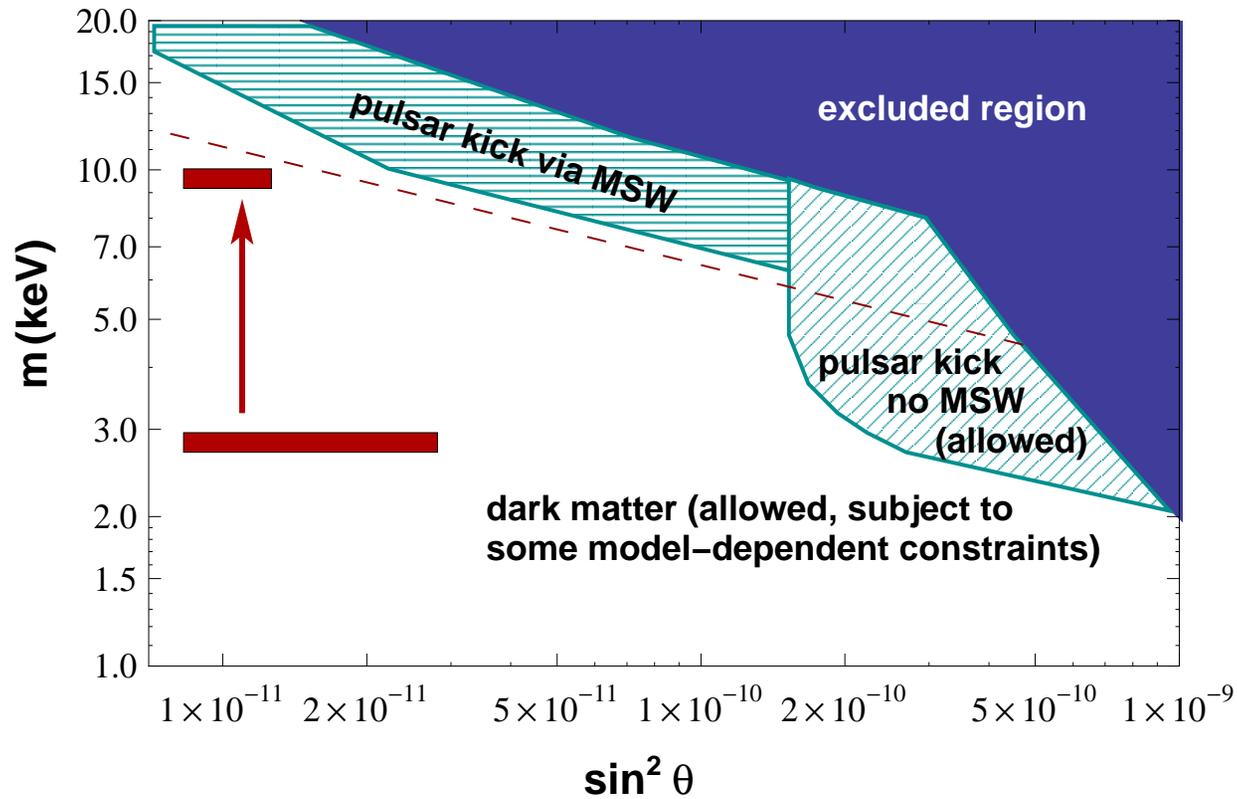

$\langle S \rangle \sim 10^2 \text{ GeV}$  (EW scale)

$M_s \sim \text{keV}$  (for stability)  $\Rightarrow h \sim 10^{-8}$

$$\Rightarrow \Omega \approx 0.2$$

The sterile neutrino momenta are red-shifted by factor  $\xi^{1/3} > 3.2$ . [AK, Petraki]

# Cooling changes the clustering properties

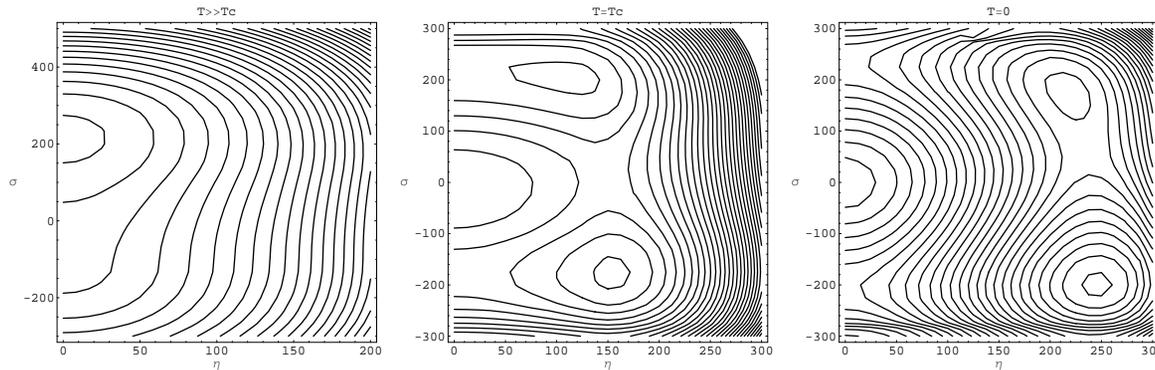

[AK, PRL **97**:241301 (2006); Petraki, AK, PRD 77, 065014 (2008); Petraki, PRD 77, 105004 (2008)]

## Implications for the EW phase transition and the LHC

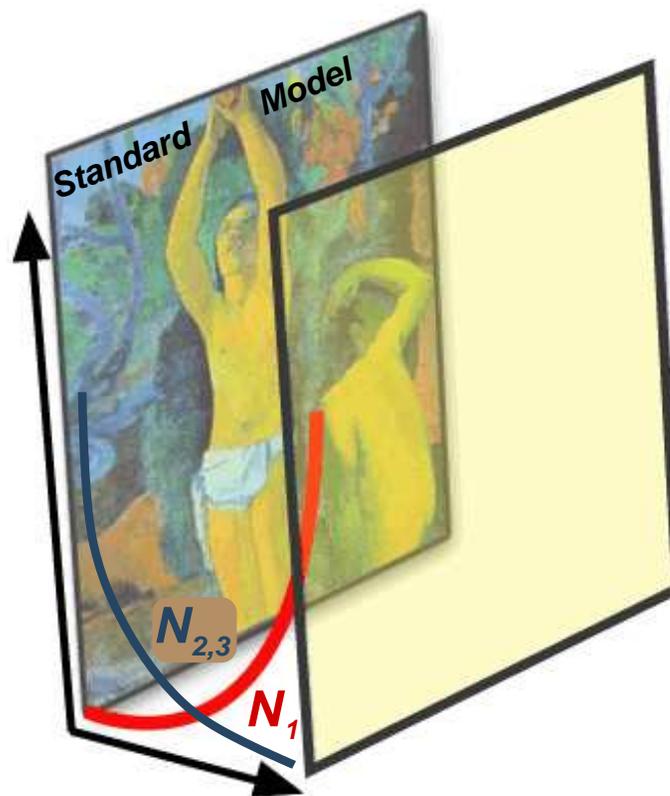

One may be able to discover the *singlet Higgs* at the LHC [Profumo, Ramsey-Musolf, G. Shaughnessy; Davoudiasl et al.; O'Connell et al.; Ramsey-Musolf, Wise]

The presence of  $S$  in the Higgs sector changes the nature of the electroweak phase transition [AK, Petraki]

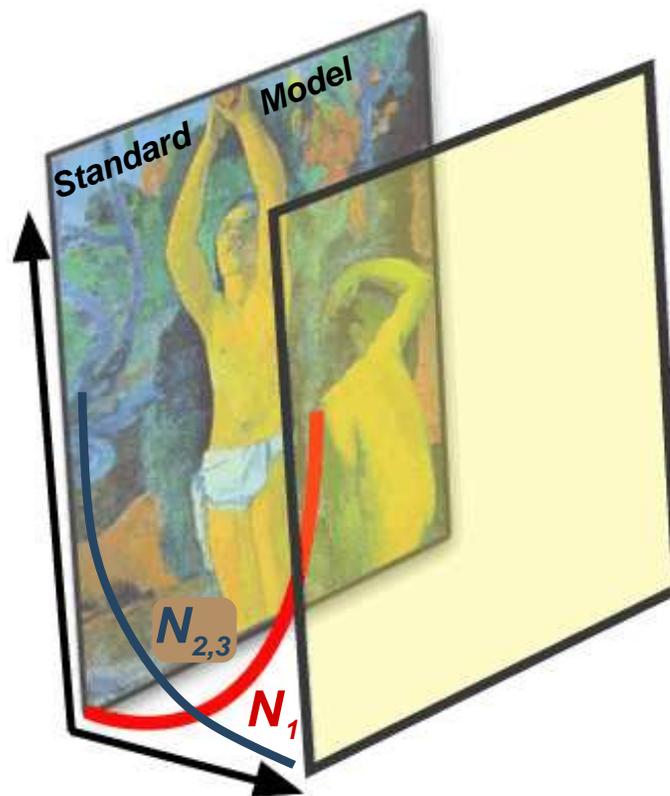

First-order transition, CP in the Higgs sector  $\implies$  **electroweak baryogenesis**

# Split seesaw

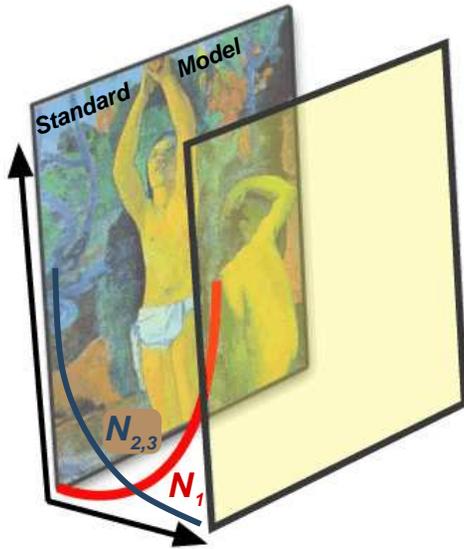

# Split seesaw

Standard Model on  $z = 0$  brane. A Dirac fermion with a bulk mass  $m$ :

$$S = \int d^4x dz M \left( i\bar{\Psi}\Gamma^A\partial_A\Psi + m\bar{\Psi}\Psi \right),$$

The zero mode:  $(i\Gamma^5\partial_5 + m)\Psi^{(0)} = 0$ .  
behaves as  $\sim \exp(\pm mz)$ . The 4D fermion:

$$\Psi_R^{(0)}(z, x) = \sqrt{\frac{2m}{e^{2ml} - 1}} \frac{1}{\sqrt{M}} e^{mz} \psi_R^{(4D)}(x).$$

Also, a  $U(1)_{(B-L)}$  gauge boson in the bulk,  
 $(B - L) = -2$  Higgs  $\phi$  on the SM  
brane. The VEV  $\langle\phi\rangle \sim 10^{15}\text{GeV}$  gives  
right-handed neutrinos heavy Majorana masses.

[AK, Takahashi, Yanagida]

## Split seesaw

Effective Yukawa coupling and the mass are suppressed:

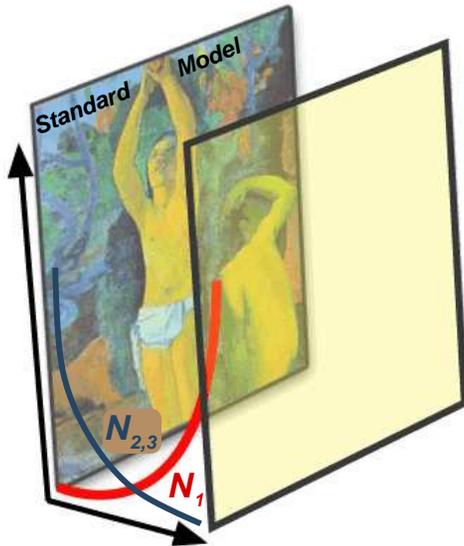

$$M_{d=4}^{(R)} = M_{d=5}^{(R)} \left( \frac{2m_i}{M(e^{2m_i \ell} - 1)} \right),$$

$$y_{d=4} = y_{d=5} \sqrt{\frac{2m_i}{M(e^{2m_i \ell} - 1)}}$$

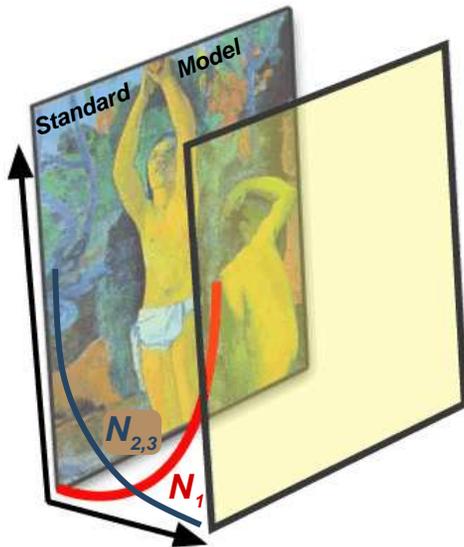

successful seesaw relation unchanged:

$$m_\nu \sim \frac{y_{d=4}^2 \langle H \rangle^2}{M_{d=4}^{(R)}} = \frac{y_{d=5}^2 \langle H \rangle^2}{M_{d=5}^{(R)}}$$

[AK, Takahashi, Yanagida]

## Split seesaw: economical, natural extension of SM

- Democracy of scales: small difference in the bulk masses  $m_i$  results in exponentially large splitting between the sterile neutrino masses.
- An rather minimal model: SM augmented by three right-handed singlets can explain
  - observed **neutrino masses**
  - **baryon asymmetry** (via leptogenesis)
  - **dark matter**

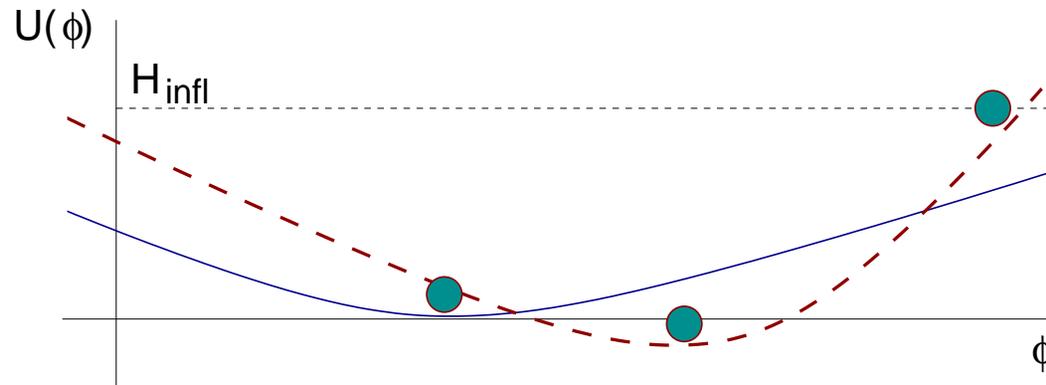

if, for example

$$M_1 = 5 \text{ keV} \text{ or } M_1 = 17 \text{ keV}, \text{ and} \\ M_{2,3} \sim 10^{15} \text{ GeV}$$

[AK, Takahashi, Yanagida]

## An alternative DM at a keV scale: string/supersymmetry moduli

- Expansion of the universe breaks supersymmetry: the effective potential acquires terms of the form  $-cH^2\phi^2$ , where  $c$  is of order one
- on average, each degree of freedom carries a non-zero energy in the de Sitter universe.

1. the minimum of the effective potential during inflation is displaced, for a light field, by a large amount ( $\sim M_{\text{Pl}}$ )
2. at the end of inflation, the field is not necessarily in the minimum of either de Sitter or flat effective potential

## Moduli problem

Oscillating scalar field is a cosmological equivalent of matter. The field starts oscillating when  $H \sim m_\phi$ , and the temperature is

$$T_\phi \sim (90/\pi^2 g_*)^{1/4} \sqrt{M_{\text{Pl}} m_\phi}.$$

The density to entropy ratio is

$$\frac{\rho_\phi}{s} \sim \frac{m_\phi^2 \phi_0^2 / 2}{(2\pi^2/45) g_* T_\phi^3} \sim 10^5 \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{M_{\text{Pl}}} \right)^2.$$

...to be compared with dark matter:

$$\frac{\rho_{\text{DM}}}{s} = 0.2 \frac{\rho_c}{s} = 3 \times 10^{-10} \text{ GeV},$$

bad discrepancy. Moreover, the universe with so much dark matter forms only one form of structures: black holes.

The density to entropy ratio is can be small enough in those (superhorion-size) patches that have  $\phi_0 \ll M_{\text{Pl}}$ :

$$\frac{\rho_\phi}{s} \sim \frac{m_\phi^2 \phi_0^2 / 2}{(2\pi^2/45)g_* T_\phi^3} \sim 10^{-9} \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{10^{-7} M_{\text{Pl}}} \right)^2 .$$

The density to entropy ratio is can be small enough in those (superhorion-size) patches that have  $\phi_0 \ll M_{\text{Pl}}$ :

$$\frac{\rho_\phi}{s} \sim \frac{m_\phi^2 \phi_0^2 / 2}{(2\pi^2/45)g_* T_\phi^3} \sim 10^{-9} \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{10^{-7} M_{\text{Pl}}} \right)^2.$$

**Can life exist in those parts of the universe where  $\Omega_{DM}/\Omega_{baryon} \gg 1$ ?**

The density to entropy ratio is can be small enough in those (superhorion-size) patches that have  $\phi_0 \ll M_{\text{Pl}}$ :

$$\frac{\rho_\phi}{s} \sim \frac{m_\phi^2 \phi_0^2 / 2}{(2\pi^2/45)g_* T_\phi^3} \sim 10^{-9} \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{10^{-7} M_{\text{Pl}}} \right)^2.$$

**Can life exist in those parts of the universe where  $\Omega_{DM}/\Omega_{baryon} \gg 1$ ?**

Structures start forming at  $T_{\text{eq}} \sim 10^5 \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{M_G} \right)^2$ . and only black holes emerge, unless  $\Omega_{DM}/\Omega_{baryon} < 10$ . [Tegmark, Aguirre, Rees, Wilczek]

The density to entropy ratio is can be small enough in those (superhorion-size) patches that have  $\phi_0 \ll M_{\text{Pl}}$ :

$$\frac{\rho_\phi}{s} \sim \frac{m_\phi^2 \phi_0^2 / 2}{(2\pi^2/45) g_* T_\phi^3} \sim 10^{-9} \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{10^{-7} M_{\text{Pl}}} \right)^2.$$

**Can life exist in those parts of the universe where  $\Omega_{\text{DM}}/\Omega_{\text{baryon}} \gg 1$ ?**

Structures start forming at  $T_{\text{eq}} \sim 10^5 \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{M_{\text{G}}} \right)^2$ . and only black holes emerge, unless  $\Omega_{\text{DM}}/\Omega_{\text{baryon}} < 10$ . [Tegmark, Aguirre, Rees, Wilczek]

Anthropic selection favors the maximal allowed value  $\phi_0$ , which corresponds to dark matter density close to the observed  $\Omega_{\text{DM}}/\Omega_{\text{baryon}}$ .

The density to entropy ratio is can be small enough in those (superhorizon-size) patches that have  $\phi_0 \ll M_{\text{Pl}}$ :

$$\frac{\rho_\phi}{s} \sim \frac{m_\phi^2 \phi_0^2 / 2}{(2\pi^2/45) g_* T_\phi^3} \sim 10^{-9} \text{ GeV} \left( \frac{m_\phi}{\text{keV}} \right)^{1/2} \left( \frac{\phi_0}{10^{-7} M_{\text{Pl}}} \right)^2.$$

Anthropic selection favors the maximal allowed value  $\phi_0$ , which corresponds to dark matter density close to the observed  $\Omega_{\text{DM}}/\Omega_{\text{baryon}}$ .

**Anthropic solution to moduli problem  $\Rightarrow$  correct amount of dark matter.**  
[AK, Loewenstein, Yanagida]

## Radiative decays of sterile neutrinos and moduli

Sterile neutrino in the mass range of interest have lifetimes **longer than the age of the universe**, but they do decay:

Photons have energies  $m/2$ : X-rays. Concentrations of dark matter emit X-rays. [Abazajian, Fuller, Tucker; Loewenstein et al., others]

Can one distinguish between sterile neutrinos and moduli? Not from the spectrum.

However, **moduli make a very cold dark matter**, while

**sterile neutrinos can have a measurable free-streaming length.**

**Conclusions: many exciting news**

- The IceCube discovery of PeV neutrinos may be able to confirm our understanding of secondary particle production from blazars.
- It can also point to decays of heavy dark matter particles!
- Dark matter at a keV mass scale is viable, well-motivated, and hinted by the recent X-ray data.
