ABSTRACT

We report results from the BICEP2 experiment, a Cosmic Microwave Background (CMB) polarimeter specifically designed to search for the signal of inflationary gravitational waves in the B -mode power spectrum around $\ell \sim 80$. The telescope comprised a 26 cm aperture all-cold refracting optical system equipped with a focal plane of 512 antenna coupled transition edge sensor (TES) 150 GHz bolometers each with temperature sensitivity of $\approx 300 \mu\text{K}_{\text{CMB}}\sqrt{s}$. BICEP2 observed from the South Pole for three seasons from 2010 to 2012. A low-foreground region of sky with an effective area of 380 square degrees was observed to a depth of 87 nK-degrees in Stokes Q and U . In this paper we describe the observations, data reduction, maps, simulations and results. We find an excess of B -mode power over the base lensed- Λ CDM expectation in the range $30 < \ell < 150$, inconsistent with the null hypothesis at a significance of $> 5\sigma$. Through jackknife tests and simulations based on detailed calibration measurements we show that systematic contamination is much smaller than the observed excess. We also estimate potential foreground signals and find that available models predict these to be considerably smaller than the observed signal. These foreground models possess no significant cross-correlation with our maps. Additionally, cross-correlating BICEP2 against 100 GHz maps from the BICEP1 experiment, the excess signal is confirmed with 3σ significance and its spectral index is found to be consistent with that of the CMB, disfavoring synchrotron or dust at 2.3σ and 2.2σ , respectively. The observed B -mode power spectrum is well-fit by a lensed- Λ CDM + tensor theoretical model with tensor/scalar ratio $r = 0.20^{+0.07}_{-0.05}$, with $r = 0$ disfavored at 7.0σ . Subtracting the best available estimate for foreground dust modifies the likelihood slightly so that $r = 0$ is disfavored at 5.9σ .

Modern cosmology in a nutshell:

Edwin Hubble

1) The universe is expanding.
(Hubble, 1920s)

2) It was once hot and dense, like the inside of the Sun.

(Alpher, Gamow, Herman, 1940s)

3) You can still see the glow!

CMB Temperature Measurements / Inflation

CMB temperature anisotropy now measured over full range of angular scales.

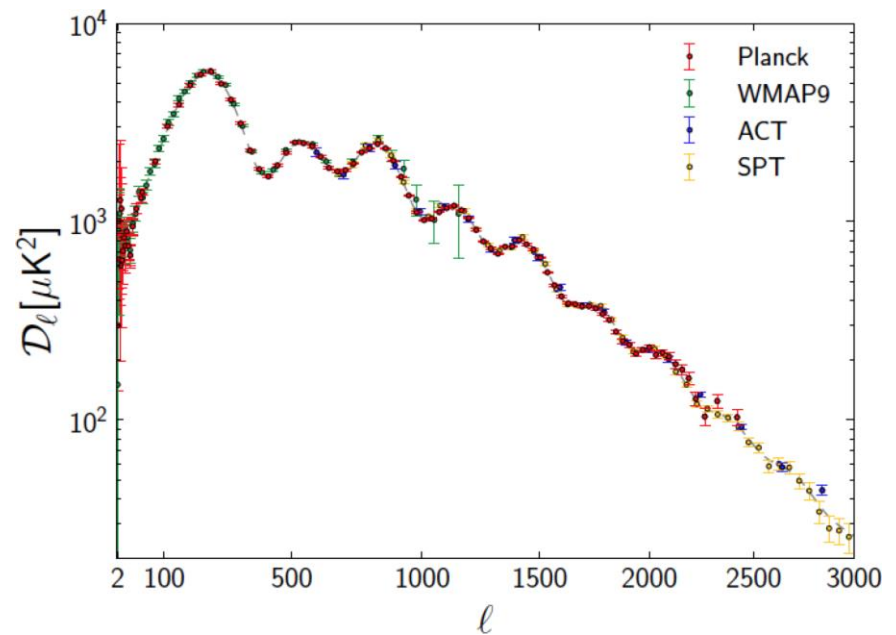

Consistent with Λ CDM paradigm(?) and constrains its parameters to sub percent accuracy.

Inflation “invented” in 1980s to explain facts about the Universe which were known or suspected.

Makes additional prediction of a background of gravitational waves (aka tensor modes) – which will imprint a specific CMB polarization pattern...

→ so-called “smoking gun”

→ amplitude tells us the energy scale at which inflation occurred

Planck Collaboration & ESA

Why Inflation?

Solves the horizon problem:
Why is the CMB nearly uniform?
How do apparently causally disconnected regions of space get set to the same temperature?

A volume much larger than our entire observable universe today was once a causally connected sub atomic spec.

Solves the flatness problem:
Why is the net spatial curvature close to zero?

Any initial spatial curvature is diluted away to undetectability by the hyper expansion.

Explains the initial perturbation spectrum: Why was it close to flat power law?

Equal amount of perturbations are injected at each step in the exponential expansion.

Solves the monopole problem:
Why do we not observe magnetic monopoles in the Universe today?

Monopoles are diluted away to undetectability.

**CMB polarization:
arises at last scattering
from local radiation quadrupole**

CMB polarization

Density Wave

E-Mode Polarization Pattern

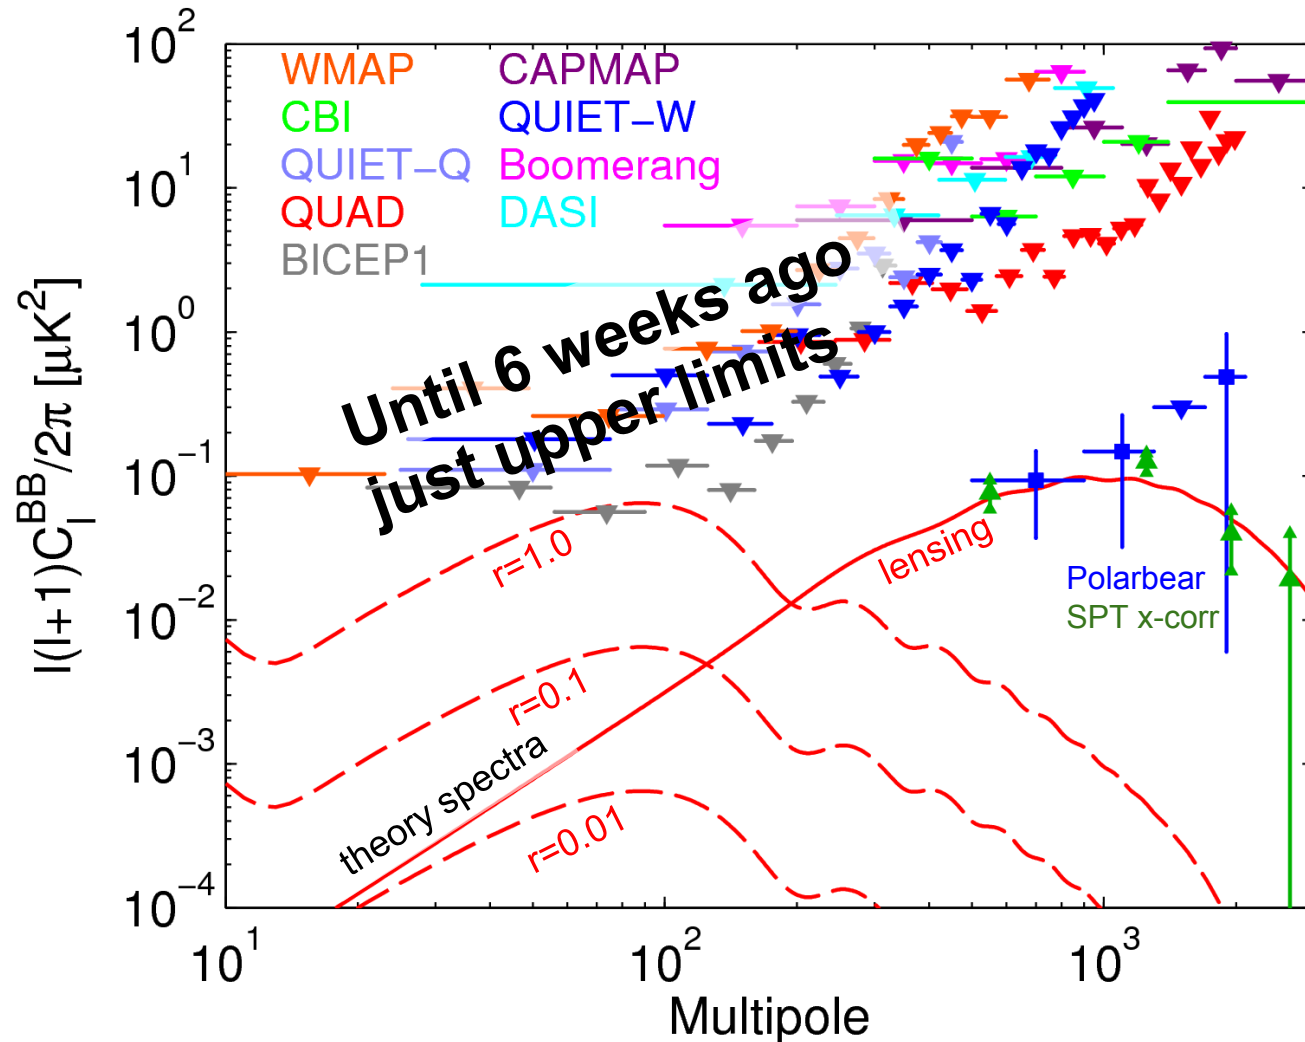

Gravitational Wave

B-Mode Polarization Pattern

The long search for Inflationary B-modes

In simple inflationary gravitational wave models the

tensor-to-scalar ratio r

is the only parameter to the B-mode spectrum.

Until recently only upper limits from searches for Inflationary B-modes

Best previous limit on r from BICEP1:

$r < 0.7$ (95% CL)

Note at high multipoles lensing B-mode dominant.

SPT x-corr: lower limits on lensing B-mode from cross correlation using the CIB

B-modes from the ground

- Deep, Concentrated coverage
 - Foreground avoidance (limited frequency)
 - Systematic control with in-situ calibration
 - Large detector count, rapid technology cycle
 - Relentless observing & large number of null tests
- powerful recipe for high-confidence initial discovery

South Pole CMB telescopes

NSF's South Pole Station:
A popular place with CMB Experimentalists!

Super dry atmosphere and 24h coverage of “Southern Hole”.
Also power, LHe, LN₂, 200 GB/day, 3 square meals, and bingo night...

BICEP2 Experimental Concept

- Small aperture
- Wide field of view
- Cold refractor

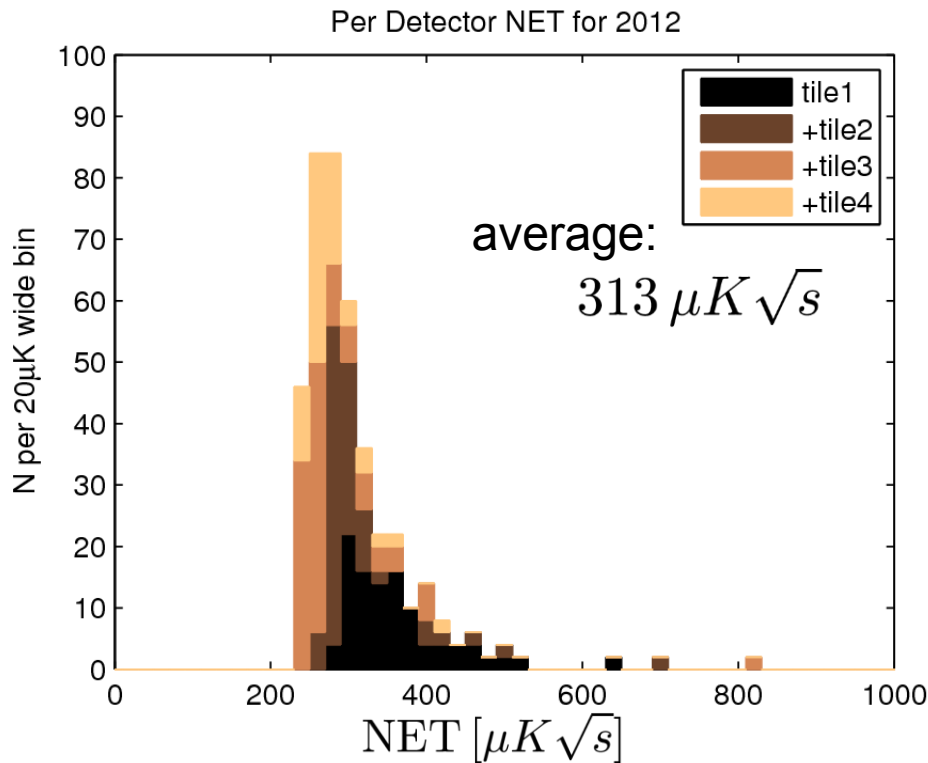

Mass-produced superconducting detectors

Slot antennas

BICEP2 Sensitivity

Histogram shows per-detector noise equivalent temperature (NET) for data taken in 2012

Our recipe for high sensitivity:

- High optical efficiency
40% end-to-end
- Cold optics
Low loading/photon noise
Low thermal conductance,
and thus low phonon noise
- High detector count

Total Sensitivity for full BICEP2 instrument: $15.8 \mu K \sqrt{s}$

Observational Strategy

Target the “Southern Hole” - a region of the sky exceptionally free of dust and synchrotron foregrounds.

Detectors tuned to 150 GHz, near the peak of the CMB’s 2.7 K blackbody spectrum.

At 150 GHz the combined dust and synchrotron spectrum is predicted to be close to minimum in the Southern Hole.

Expected foreground contamination of the B-mode power: $r \leq \sim 0.01$.

BICEP2 on the Sky

Projection of the BICEP2 focal plane on the sky

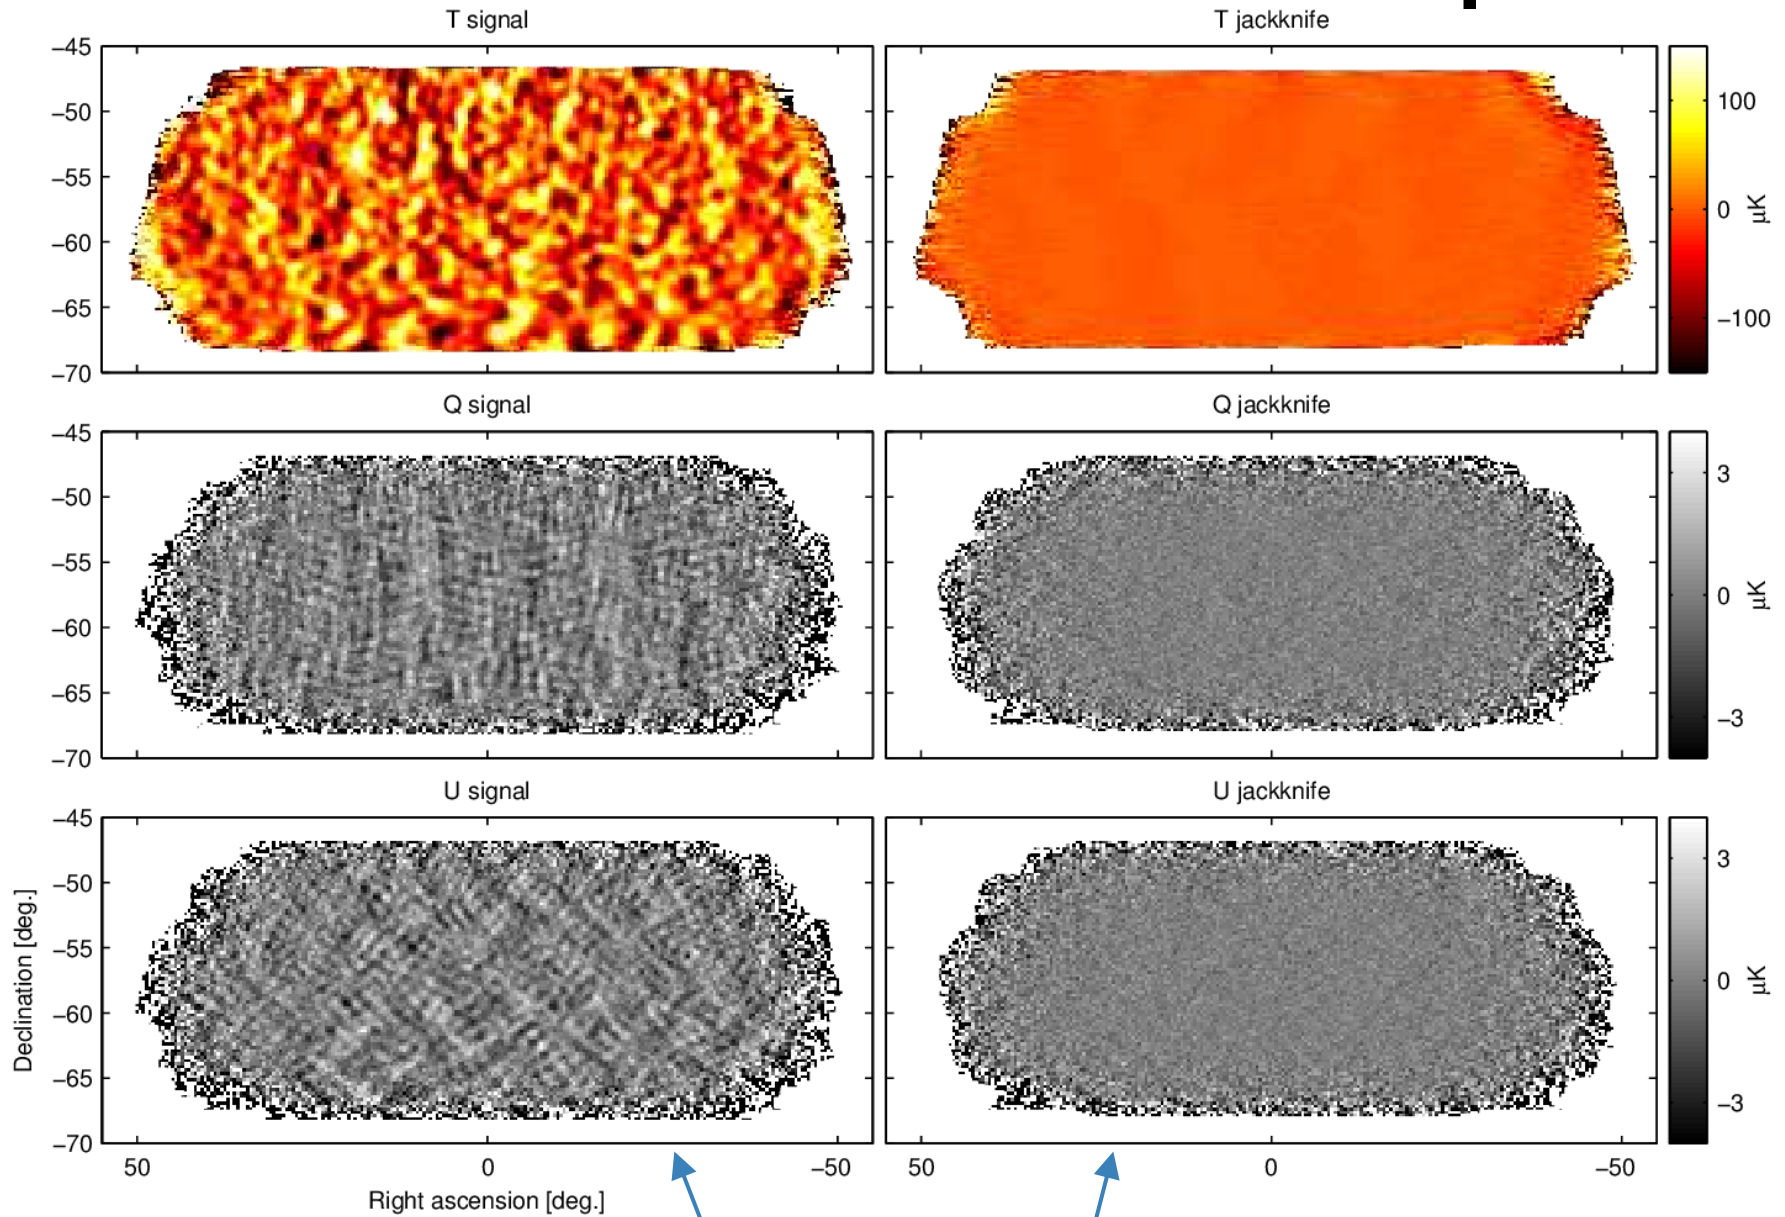

The focal plane is 20 degrees across

Background is the CMB temperature map as measured with BICEP2

BICEP2 3-year Data Set

BICEP2 T and Stokes Q/U Maps

Total Polarization

B-mode Contribution

BICEP2 B-mode signal

Scale: $1.7 \mu K$

Apply purification operation to Q/U maps which leaves only pure B-modes
(given all timestream filterings etc.)

B-mode Contribution

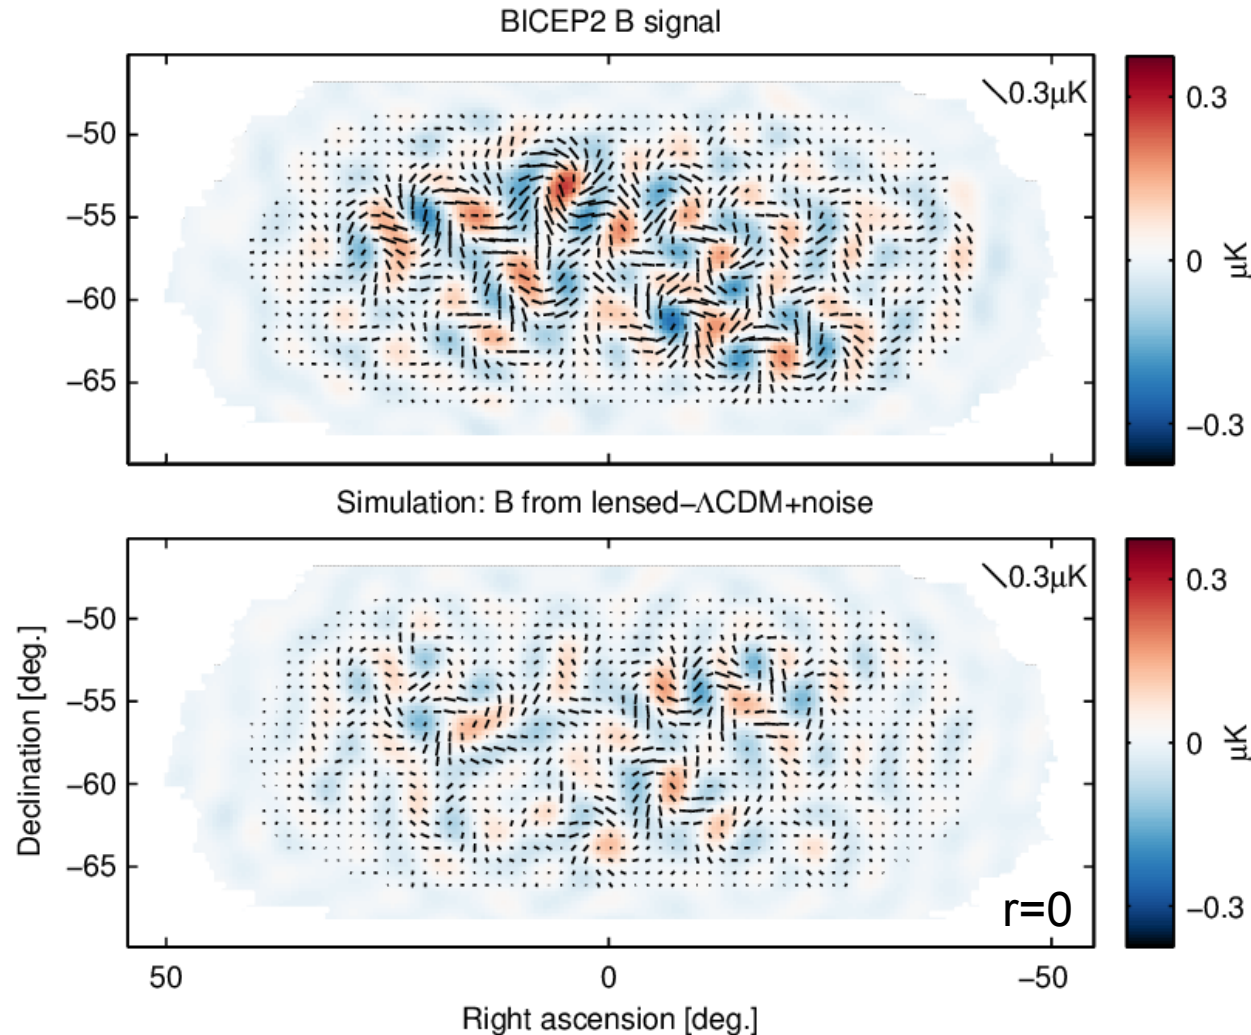

BICEP2 B-mode signal

Scale: $0.3 \mu K$

Zoom in by factor 6 – see “swirly” B-mode

B-mode Map vs. Simulation

Analysis “calibrated” using lensed- Λ CDM+noise simulations.

The simulations repeat the full observation at the timestream level - including all filtering operations.

We perform various filtering operations: Use the sims to correct for these

Also use the sims to derive the final uncertainties (error bars)

BICEP2 B-mode Power Spectrum

- B-mode power spectrum
- temporal split jackknife
- lensed- Λ CDM
- - - $r=0.2$

B-mode power spectrum estimated from Q&U maps, including map based “purification” to avoid $E \rightarrow B$ mixing

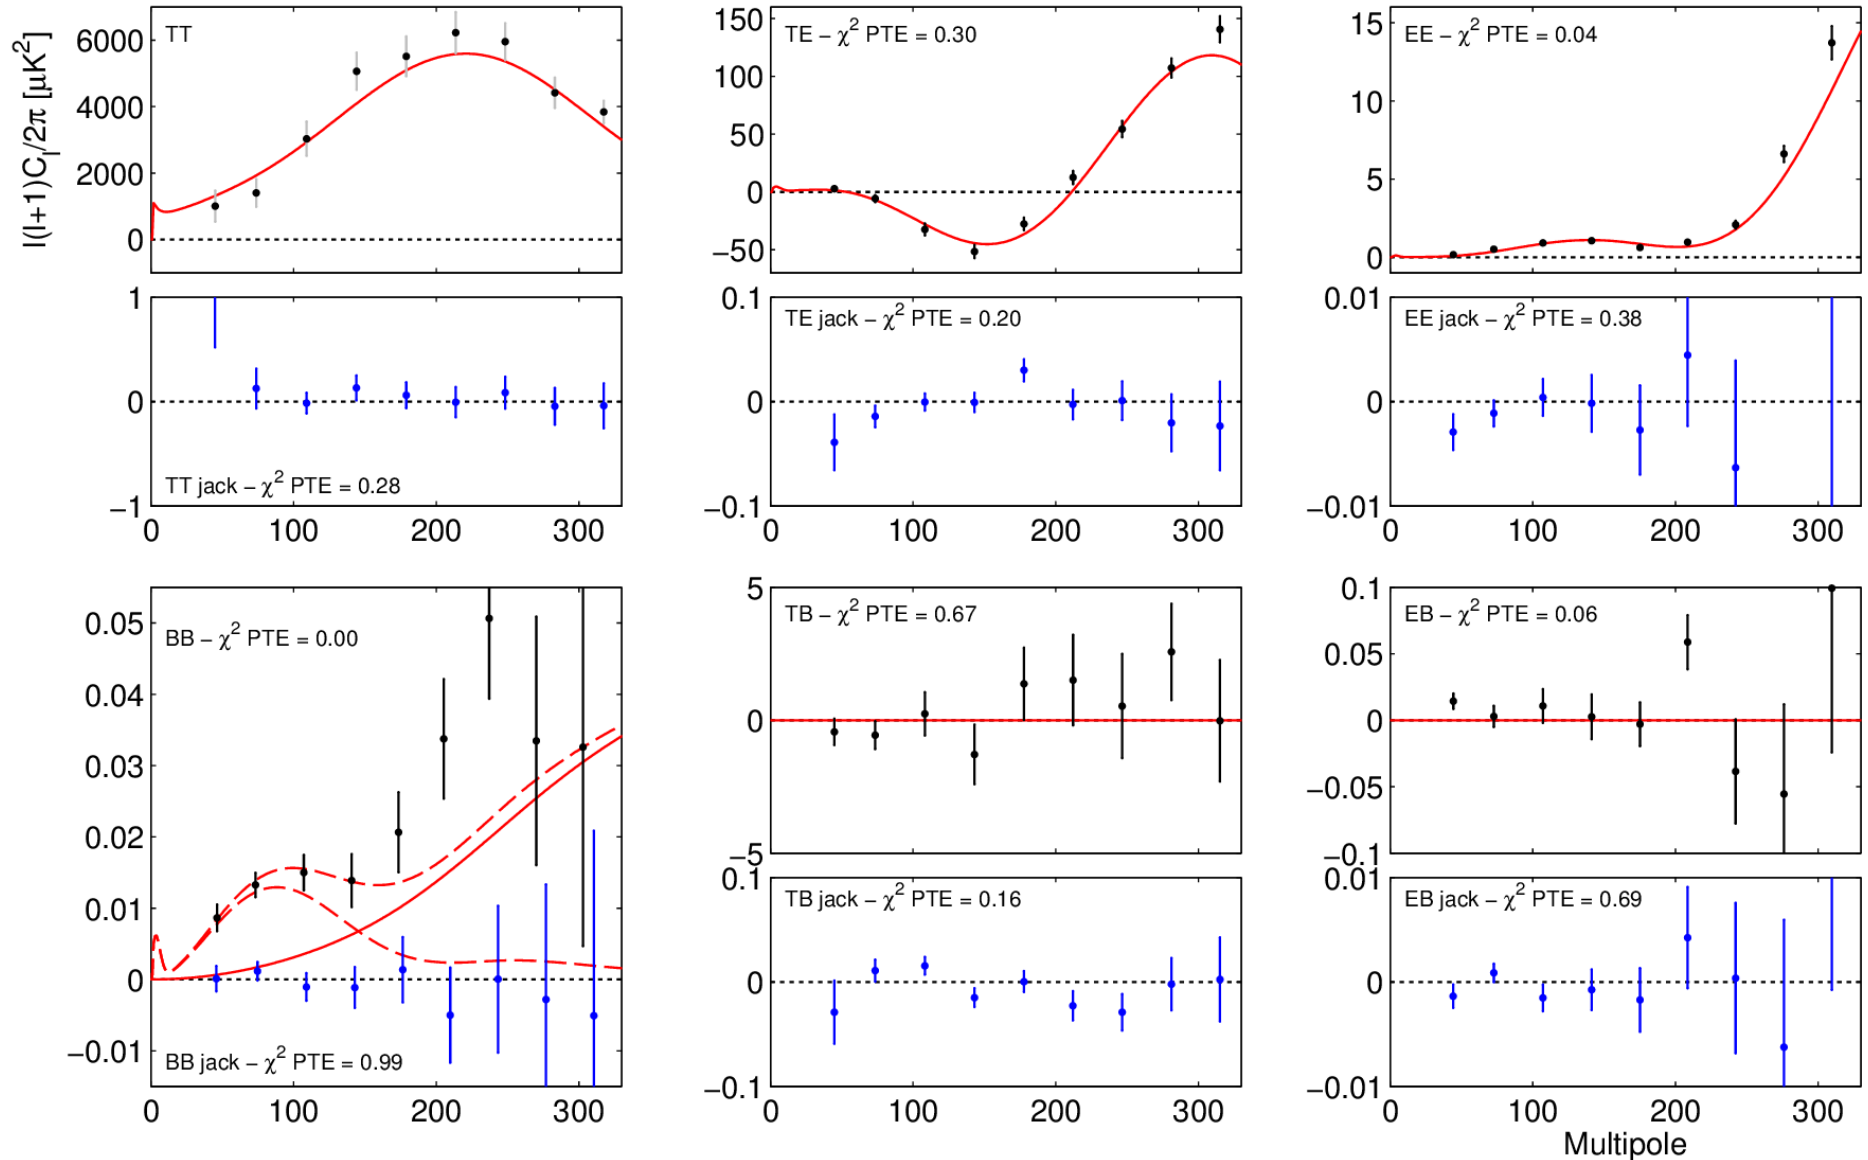

Consistent with lensing expectation at higher l . (yes – a few points are high but not excessively...)

At low l excess over lensed- Λ CDM with high signal-to-noise.

For the hypothesis that the measured band powers come from lensed- Λ CDM we find:

χ^2 PTE	1.3×10^{-7}
significance	5.3σ

Temperature and Polarization Spectra

● power spectra
 ● temporal split jackknife
 — lensed- Λ CDM
 - - $r=0.2$

Splits the 4 boresight rotations

Amplifies differential pointing in comparison to fully added data. Important check of deprojection. See later slides.

Splits by time

Checks for contamination on long (“Temporal Split”) and short (“Scan Dir”) timescales. Short timescales probe detector transfer functions.

Splits by channel selection

Checks for contamination in channel subgroups, divided by focal plane location, tile location, and readout electronics grouping

Splits by possible external contamination

Checks for contamination from ground-fixed signals, such as polarized sky or magnetic fields, or the moon

Splits to check intrinsic detector properties

Checks for contamination from detectors with best/worst differential pointing. “Tile/dk” divides the data by the orientation of the detector on the sky.

Systematics paper nearly ready – and see Chris Sheehy poster

**Detailed description in
companion Instrument Paper**

Detector Polarization Calibration

Channel 235

Polarized Dust Foreground Projections

The BICEP2 region is chosen to have very low foreground emission.

Use various models of polarized dust emission to estimate foregrounds.

All dust auto spectra well below observed signal level.

Cross spectra consistent with zero.

Cross Correlation with BICEP1

Though less sensitive, BICEP1 applied **different technology** (systematics control) and **multiple colors** (foreground control) to the **same sky**.

BICEP2: Phased antenna array and TES readout
150 GHz

BICEP1: Feedhorns
and NTD readout
150 and 100 GHz

Cross-correlations with both colors are **consistent** with the B2 auto spectrum

Cross with BICEP1₁₀₀ shows **~3σ** detection of BB power

Spectral Index of the B-mode Signal

Likelihood ratio test: consistent with CMB spectrum, disfavor pure dust/sync at **2.2/2.3 σ**

Comparison of B2 auto with B2₁₅₀ × B1₁₀₀ constrains signal frequency dependence, independent of foreground projections

If **dust**, expect little cross-correlation

If **synchrotron**, expect cross higher than auto

Cross Spectra between 3 Experiments

Form cross spectrum between BICEP2 and
BICEP1 combined (100 + 150 GHz):

BICEP2 auto spectrum compatible with
B2xB1c cross spectrum
~3 σ evidence of excess power in the
cross spectrum

Additionally form cross spectrum with
2 years of data from *Keck Array*, the
successor to BICEP2

Excess power is also evident in the
B2xKeck cross spectrum

Cross spectra:
**Powerful additional evidence against a
systematic origin of the apparent signal**

Constraint on Tensor-to-scalar Ratio r

Substantial excess power in the region where the inflationary gravitational wave signal is expected to peak

Find the most likely value of the tensor-to-scalar ratio r

Apply “direct likelihood” method, uses:

- lensed- Λ CDM + noise simulations
- weighted version of the 5 bandpowers
- B-mode sims scaled to various levels of r ($n_T=0$)

Within this simplistic model we find:

$r = 0.2$ with uncertainties dominated by sample variance

PTE of fit to data: 0.9

→ model is perfectly acceptable fit to the data

$r = 0$ ruled out at 7.0σ

Constraint on r under Foreground Projections

Adjust likelihood curve by subtracting the dust projection auto and cross spectra from our bandpowers:

Probability that each of these models reflect reality hard to assess

DDM2 uses all publicly available information from Planck - modifies constraint to $r = 0.16^{+0.06}_{-0.05}$
 $r = 0$ ruled out at 5.9σ

Dust contribution is largest in the first bandpower. Deweighting this bin would lead to less deviation from our base result.

Compatibility with Temperature Based Limits on r

Using temperature data over a wide range of angular scales limits on r have been set:

SPT+WMAP+BAO+ H_0 : $r < 0.11$

Planck+SPT+ACT+WMAP_{pol} : $r < 0.11$
(95% CL)

However, $r=0.2$ just makes a small change to the temperature spectrum.

(In this plot $r=0.2$ simply added to Planck best fit model with no re-optimization of other parameters)

Compatibility with Indirect Limits on r ?

Constraint on r *with running allowed*:

The apparent tension can be relieved with various extensions to lensed Λ CDM.

Example: running of the spectral index

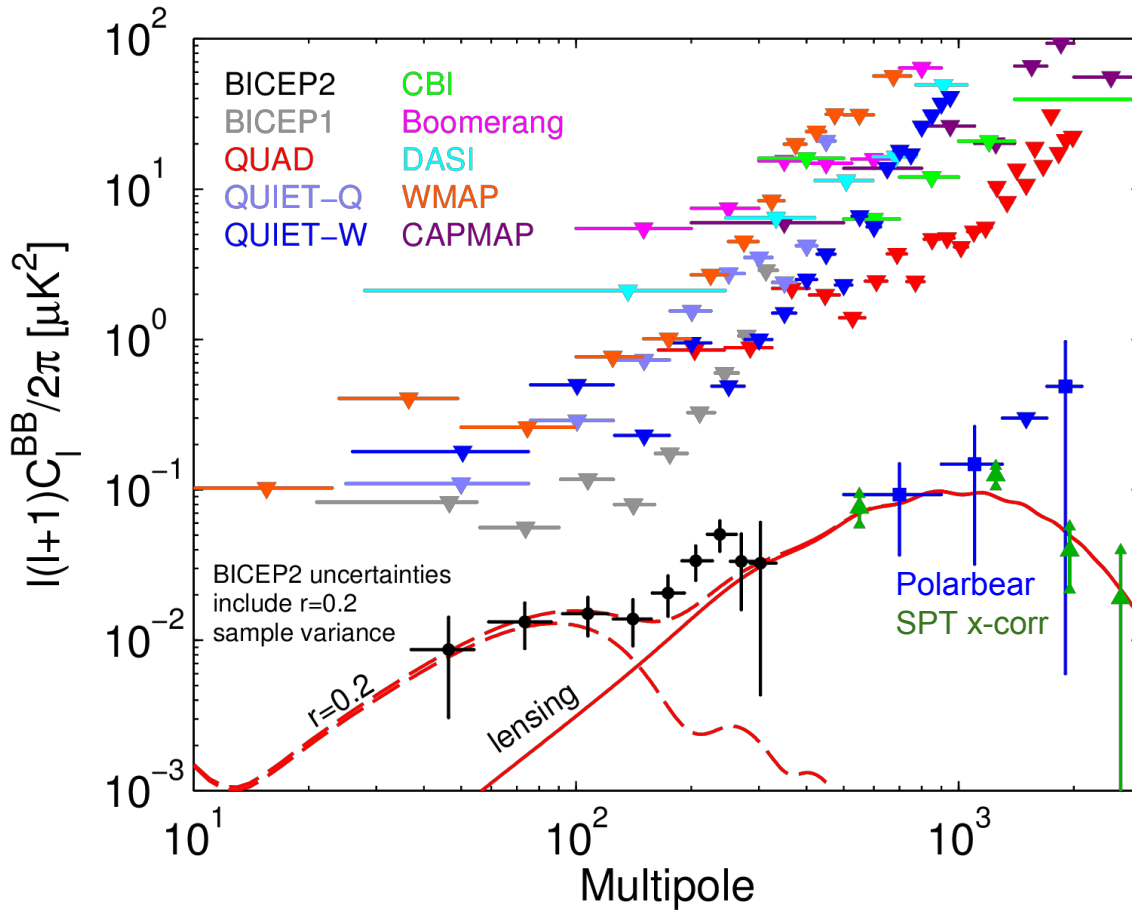

Planck likelihood chains for lensed Λ CDM + *tensors* + *running*

Same chains, importance sampled with the BICEP2 r likelihood

Other possibilities within Λ CDM?...

Conclusions

BICEP2 and upper limits from other experiments:

<http://bicepkeck.org>

Most sensitive polarization maps ever made

Power spectra perfectly consistent with lensed- Λ CDM except:
5.2 σ excess in the B-mode spectrum at low multipoles!

Extensive studies and jackknife test strongly argue against systematics as the origin

Foregrounds do not appear to be a large fraction of the signal:

- foreground projections
- lack of cross correlations
- CMB-like spectral index
- shape of the B-mode spectrum

Constraint on tensor-to-scalar ratio r in simple inflationary model:
 $r = 0.20^{+0.07}_{-0.05}$

With $r=0$ is ruled out at 7.0 σ .

What's Next?

Confirm:

- Keck Array 2012/13 results coming soon (within few months)
- Planck may be able to confirm at either reionization ($\ell < 10$) or recombination ($\ell = 80$) bump – or show it's all dust...
- SPTpol has data in the can over same sky patch at 100 and 150 GHz
 - Should be able to see signal alone and/or in cross correlation with BICEP2/Keck
- Keck 2014 running right now with two 100 GHz receivers – will rapidly surpass BICEP1 100 GHz sensitivity.
- Polarbear, ACTpol, ABS running...
- EBEX has data in the can... Spider will fly later this year... plus many others...

Refine:

- Need more sky/sensitivity to reduce uncertainty on r
- Need longer lever arm to measure tensor spectral index n_T
 - De-lense to push to higher ℓ
 - Big sky to push to lower ℓ
- Add small apertures to DoE S4? Renewed interest in future space mission? Ground based spinners? (Cf. CLASS)
