Explaining the Baryon Asymmetry

- Observed baryon asymmetry: \[ Y_B \equiv \frac{n_q - n_{\bar{q}}}{3s} \sim 10^{-10} \]

- Microphysical mechanism for generation of the asymmetry must satisfy the “Sakharov conditions”:
  1. \( B \) – violation
  2. \( C \)– and \( CP \)–violation
  3. “Arrow of time”

- Possible at the electroweak phase transition:

Requires physics BSM

Bernreuther, 0205279
Electroweak Baryogenesis in SUSY

**SUSY can help...**

New scalars contribute cubic terms to effective potential

\[
V_1(T > 0) = V_1(T = 0) + \frac{T^2}{2\pi^2} \sum_i n_i J_\pm \left( \frac{m_i^2}{T^2} \right)
\]

High-T expansion for bosons:

\[
\approx -\frac{\pi^4}{45} + \frac{\pi^2 m^2}{12T^2} - \frac{\pi}{6} \left( \frac{m^2}{T^2} \right)^{3/2} + \ldots
\]
(\textbf{Electroweak Baryogenesis in SUSY})

...but the MSSM is in trouble

- Light stops increase gluon-gluon fusion Higgs production cross-section
  \[ m_{\tilde{t}_1} \lesssim 117 \text{ GeV} \]
  \textit{Menon +Morrissey, 0903.3038; however, see 1207.6330 for a possible work-around}

- Highly constrained by direct searches
  \textit{Krizka et al, 1212.4856, Delgado et al, 1212.6847; however, see 1303.4414 for a possible work-around}

Carena et al, 1207.6330

Baryogenesis in the NMSSM

How about the NMSSM?

- Tree-level Higgs mass enhancement: \( m_{h_1}^2 \leq \left( \cos^2 2\beta + \frac{2\lambda^2 \sin^2 2\beta}{g_1^2 + g_2^2} \right) m_Z^2 \).
- No mu problem: \( \mu = \lambda v_s \).
- New singlet fermion + complex scalar

\[
V_0(h_u, h_d, s) = \frac{1}{32} (g_1^2 + g_2^2) (h_u^2 - h_d^2)^2 + \frac{1}{4} \kappa^2 s^4 - \frac{1}{2} \lambda \kappa s^2 h_u h_d + \frac{1}{4} \lambda^2 (h_d h_u^2 + s^2 (h_d^2 + h_u^2))
\]
\[
+ \frac{\sqrt{2}}{6} \kappa A s^3 - \frac{\sqrt{2}}{2} \lambda A h_u h_d + \frac{1}{2} m_d^2 h_d^2 + \frac{1}{2} m_u^2 h_u^2 + \frac{1}{2} m_s^2 s^2.
\]

\( \rightarrow \) Cubic terms at tree-level

\( \rightarrow \) Potentially rich phase transition phenomenology
What are the properties of the PT in viable regions of parameter space?

Baryogenesis? Implications for cosmology? Observable signatures?

Focus on regions with: moderately heavy (~1 – 2 TeV) stops, ~125 GeV SM-like Higgs, viable DM, spectrum OK w/LHC

Our method: Effective Field Theory approach

\[ V_1(T=0) = \sum_i \frac{\pm n_i}{64\pi^2} m_i^4 \left[ \log \left( \frac{m_i^2}{\Lambda^2} \right) - c \right] \]

Heavy stops \( \rightarrow \) large logs
What we’ve found:

Variety of symmetry breaking patterns possible

-Strong 1st order singlet transitions common. Occur at higher temperatures

-Found several points with strong 1st order 1-step EWPT. Typically large $\lambda$, $A_\lambda$, small $\tan \beta$, moderate $\mu$ (see e.g. 1309.5091 for other possibilities)
Baryogenesis in the NMSSM

What we’ve found:

Electroweak baryogenesis can be realized across this region of parameter space

Sample point:

- General feature: new light states (singlet-like scalar/pseudoscalar; fermions) potentially accessible by LHC 14 and DM experiments
Baryogenesis in the NMSSM

What we’ve found:

Bubble walls tend not to run away

Broken phase vanishes in mean field potential $\rightarrow$ no runaway solution (Bodeker+Moore, 0903.4099)

$\rightarrow$ Gravity waves typically not detectable for points we considered

$\rightarrow$ EWB looks promising!
Summary and Conclusions

- NMSSM regions with a SM-like 125 GeV Higgs, moderately heavy stops, and viable DM can feature strongly 1\textsuperscript{st} order phase transitions.

- Singlet transitions common – may open the door for alternative baryogenesis scenarios.

- Bubble walls tend not to run away. Also, other parameters relevant for EWB look promising.

- Much of the interesting parameter space of this scenario will be probed soon!

Constraints on Light Stops

Light stops constrained by LHC searches (Krizka et al, 1212.4856, Delgado et al, 1212.6847)

For $m_{\tilde{t}} < m_t + m_{\chi_1^0}$ relevant decay channels are e.g. $\tilde{t} \rightarrow \chi_1^0 b W^+$, $\tilde{t} \rightarrow \chi_1^0 c$, $\tilde{t} \rightarrow \chi_1^0 b \ell \nu$

Razor searches in particular (unofficially) rule out the light stop scenario

Pending official analysis

May be a small window between 120 GeV and 140 GeV if a light stau allows $\tilde{t} \rightarrow \tilde{\tau}^+ \nu b$ (Carena et al, 1303.4414)
Trilepton constraints on Higgsino-singlino scenario are substantially weaker than usual wino-bino case.
