

# Discussion:

## $B \rightarrow K^{(*)}\ell^+\ell^-$ SM predictions

David M. Straub

Junior Research Group “New Physics”  
Excellence Cluster Universe, Munich

# Disclaimer

- ▶ These are some plots and comments to aid the discussion, not a seminar
  - ▶ References missing
  - ▶ Numerics are preliminary
  - ▶ All numbers (including mistakes!) obtained by me, comments about other people's work might be inaccurate
  - ▶ Slides do not make much sense by themselves (please contact me if you have questions, [david.straub@tum.de](mailto:david.straub@tum.de))
- ▶ Thanks to Aoife Bharucha for providing preliminary LCSR results

# Outline

1 High  $q^2$  = low recoil

2 Low  $q^2$  = large recoil

# High $q^2$ : ingredients

1. Effective Wilson coefficients
2. Form factors
3. Violation of quark-hadron duality (resonances ...)

# Effective Wilson coefficients

- ▶ perturbative uncertainties are small
- ▶  $C_{7,9}^{\text{eff}}$ : important to include two-loop virtual corrections!  
[Asatryan et al., Seidel, Beneke/Feldmann/Seidel, Greub/Pilipp/Schubach, ...]
  - ▶ Lead to a  $O(10\%)$  **suppression** of the BRs
  - ▶ Attention – different sign convention of [Seidel] vs. [Asatryan et al.] !
  - ▶ **Not** included in [Bouchard et al. 1306.0434] !
  - ▶ Included in [Bobeth et al., Beaujean et al., Altmannshofer et al., Horgan et al.]
  - ▶ Apparently **not** included in today's LHCb paper ...

# Form factors

- ▶ We finally have lattice FFs for  $B \rightarrow K$ ,  $B \rightarrow K^*$  and  $B_s \rightarrow \phi$
- ▶ An independent confirmation by other lattice groups would be useful
- ▶ But old-school LCSR extrapolations are clearly deprecated, they depend a lot on the parametrization chosen
- ▶ Combining LCSR & lattice can instead be very useful, e.g. to fix/cross-check the normalization

# Quark-hadron duality

This will be discussed in the resonances session, but to summarize Beylich/Buchalla/Feldmann [Beylich et al. 1101.5118] :

- ▶ The precise form of the “oscillation” depends on your model
- ▶ The  $q^2$ -integrated obs. *do not*, because an OPE exists
- ▶ Remaining uncertainty in the integrated rate estimated at  $\pm 2\%$ : negligible compared to FF uncertainty

Suggested treatment when looking for NP:

- ▶ Use large bin  $[15 \text{ GeV}^2, q_{\text{max}}^2]$  and use OPE

# Quark-hadron duality

This will be discussed in the resonances session, but to summarize Beylich/Buchalla/Feldmann [Beylich et al. 1101.5118]:

- ▶ The precise form of the “oscillation” depends on your model
- ▶ The  $q^2$ -integrated obs. *do not*, because an OPE exists
- ▶ Remaining uncertainty in the integrated rate estimated at  $\pm 2\%$ : negligible compared to FF uncertainty

Suggested treatment when looking for NP:

- ▶ Use large bin  $[15 \text{ GeV}^2, q_{\text{max}}^2]$  and use OPE
- ▶ Fitting the  $q^2$  dependence can then serve to test your model of the resonances

## Now: numerics

- ▶ Lattice  $B \rightarrow K$  and  $B \rightarrow K^*$  FFs including all (known) error correlations
- ▶ Including parametric uncertainties (CKM,  $m_{b,c}$ , ...)
- ▶ All errors added in quadrature
- ▶ Neglecting duality violation following Beylich et al.
- ▶ Using [16–19] bin for  $B \rightarrow K^* \mu \mu$  because data on [15–19] not yet available
- ▶ [15–19] bin for  $B \rightarrow K \mu \mu$  available since Moriond
- ▶ Will only show LHCb experimental data (sorry)

NB, the following plots are inspired by a similar plot by Mitesh Patel at Moriond and a subsequent one by Wolfgang Altmannshofer

## Numerics at high $q^2$ : lattice FFs

- Normalized to SM central value; light boxes:  $\text{SM} \pm 1\sigma$ ; dark boxes: parametric uncertainties only; empty boxes: “neglecting” parameter correlations; error bars: LHCb data

## High $q^2$ : summary

- ▶ Use lattice FFs
- ▶ Don't forget NNLO virtual corrections
- ▶ Use large bin  $[15 \text{ GeV}^2, q_{\text{max}}^2]$  & OPE
- ▶ Combined fit to low & high  $q^2$  form factors can serve as consistency check
- ▶ BR uncertainties start to be dominated by CKM
- ▶  $\text{BR}(B \rightarrow K \mu \mu)_{[15,22]}$  is consistent with the SM!

# Outline

1 High  $q^2$  = low recoil

2 Low  $q^2$  = large recoil

## Low $q^2$ : ingredients

1. Effective Wilson coefficients (see high  $q^2$ )
2. Form factors
3. QCDF corrections in the  $m_b \rightarrow \infty$  limit
4. Non-factorizable power corrections

# Form factors

## Soft vs. full

- ▶ 7 full FFs reduce to 2 soft FFs  $\xi_{\perp, \parallel}$  in the heavy quark, large energy limit
- ▶ Difference between soft FFs & full FFs = factorizable power corrections

# Form factors

## Soft vs. full

- ▶ 7 full FFs reduce to 2 soft FFs  $\xi_{\perp, \parallel}$  in the heavy quark, large energy limit
- ▶ Difference between soft FFs & full FFs = factorizable power corrections

## LCSR form factors: 2 approaches

- ▶ Ball-Zwicky: requires  $K^*$  meson LCDA
- ▶ Khodjamirian-Mannel-Pivovarov-Wang: requires  $B$  meson LCDA

# Form factors

## Soft vs. full

- ▶ 7 full FFs reduce to 2 soft FFs  $\xi_{\perp, \parallel}$  in the heavy quark, large energy limit
- ▶ Difference between soft FFs & full FFs = factorizable power corrections

## LCSR form factors: 2 approaches

- ▶ Ball-Zwicky: requires  $K^*$  meson LCDA
- ▶ Khodjamirian-Mannel-Pivovarov-Wang: requires  $B$  meson LCDA

## Parametrization & correlations

- ▶ Fitting the 7 form factors to (2 or 3-parameter) parametrizations, fit parameters typically highly correlated
- ▶ Including these correlations is crucial in observables involving ratios of FFs

## QCD factorization

- Factorizable corrections: expressing the 7 full FFs in terms of the soft FFs. Not to be included when using full FFs
- Non-factorizable corrections: weak annihilation, spectator scattering, and form factor correction. NLO:

- QCDF breaks down at  $q^2 \sim 6 \text{ GeV}^2$  and cannot be trusted beyond (to be discussed)

# Power corrections

- ▶ “factorizable PC”: difference between soft & full FFs
- ▶ Non-factorizable PC: some partial results using LCSR [Lyon & Zwicky, Khodjamirian et al.]

# Estimating unknown power corrections

Possibilities:

1. Multiplying each spin amplitude by a fudge factor  $f = (1 \pm \delta_{\text{pc}})$ , e.g.  $\delta_{\text{pc}} = 0.1$ 
  - Problematic for observables that cross 0 ( $A_{\text{FB}}$ ,  $S_4$ ,  $S_5$ ) – emphasized by Sebastian Jäger at LHCb Implications Workshop 2013
2. Additive correction to spin amplitudes
  - In the following: multiply  $C_9^{\text{SM}}$  by  $f = (1 \pm \delta_{\text{pc}})$ , with  $\delta_{\text{pc}}$  different for each spin amplitude
  - Other approaches? Multiply  $C_7$ ? Helicity hierarchies of power corrections? (Camalich & Jäger)

## Now: numerics

- ▶ Unknown non-factorizable corrections accounted for by  $C_9^{\text{SM}}(1 \pm \delta_{\text{pc}})$  with  $\delta_{\text{pc}} = 20\%$  different for each spin amplitude
- ▶ All errors added in quadrature
- ▶ Only LHCb data shown

# Ball-Zwicky full FFs w/ correlations

- Dark:  $\delta_{\text{pc}} = 0$ , light:  $\delta_{\text{pc}} = 0.2$ . Following plots normalized to these central values

# Combined fit to Ball-Zwicky & lattice FFs

# KMPW soft FFs (DMV-like)

► Perfectly consistent;  $P'_{4,5}$  sensitive to PCs (fact. & non-fact.)

# KMPW soft FFs (DMV-like)

- ▶ Perfectly consistent;  $P'_{4,5}$  sensitive to PCs (fact. & non-fact.)
- ▶ Comparing to numerics of DMV

# KMPW full FFs, no correlations

- Huge (unphysical) uncertainties if fit correlations/FF constraints not taken into account

# Camalich/Jäger soft FFs with and without $a + bq^2$

- Low BR due to normalization of  $\xi_{\perp}(0)$  from  $B \rightarrow K^* \gamma$  exp.

## Low $q^2$ : summary

- ▶ Main issues: form factors & estimate of unknown PCs
- ▶ Factorizable PCs taken into account when full FFs are used
- ▶ Correlation between FF fit parameters are crucial when using full FFs
