NuFACT 2014 (Glasgow, Scotland, UK)

# Inputs to $\nu_\mu \rightarrow \nu_e$ oscillation measurements

**Observation** fitted to prediction templates to extract parameters ( $\Delta m^2, \theta, \delta$ )

$$N_{FD}(E_\nu) = \Phi_{\nu_\mu} \times P_{\nu_\mu \rightarrow \nu_e}(E_\nu) \times \sigma_{\nu_e}(E_\nu) \times \mathbf{R}(E_\nu, E_{\text{visible}}) + N_{bg}$$

The diagram illustrates the components of the prediction equation  $N_{FD}(E_\nu) = \Phi_{\nu_\mu} \times P_{\nu_\mu \rightarrow \nu_e}(E_\nu) \times \sigma_{\nu_e}(E_\nu) \times \mathbf{R}(E_\nu, E_{\text{visible}}) + N_{bg}$ . Each term is annotated with an arrow and a label:

- $\Phi_{\nu_\mu}$ : flux prediction
- $P_{\nu_\mu \rightarrow \nu_e}(E_\nu)$ : oscillation probability
- $\sigma_{\nu_e}(E_\nu)$ :  $\nu_e$  cross-section (highlighted in a red box)
- $\mathbf{R}(E_\nu, E_{\text{visible}})$ : detector effects smearing matrix
- $N_{bg}$ : background (highlighted in a red box)

Additional annotations include:

- A red arrow points from the text " $\nu_e$  cross-section" to the  $\sigma_{\nu_e}(E_\nu)$  term.
- A red arrow points from the text "accelerator  $\nu_\mu$  beams typically have an intrinsic  $\sim 1\%$   $\nu_e$  component" to the  $N_{bg}$  term.

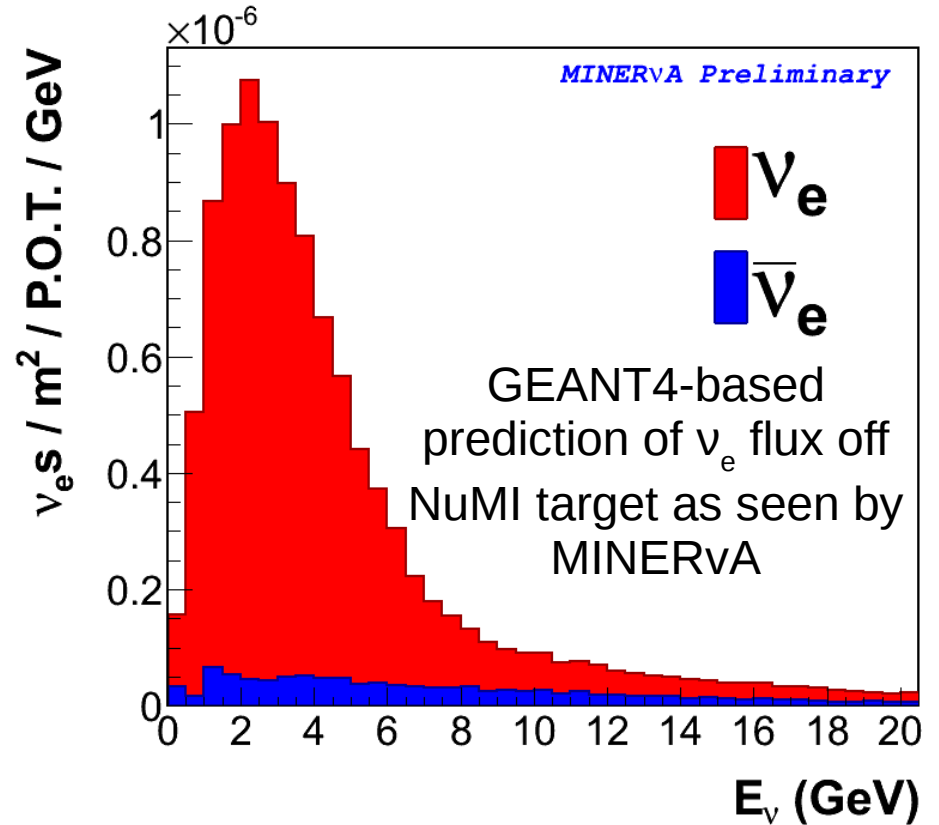

The  $\nu_e$  cross-section enters twice in the prediction: so a precision result necessitates a precision input.

# Signal definition

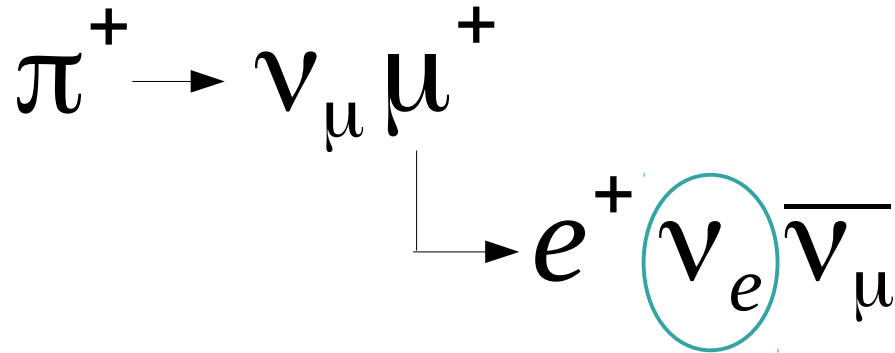

Electron neutrinos from beam muon decay.  
About 10%  $\bar{\nu}_e$ . MINERvA is not magnetized...  
so  $e^+$  looks like  $e^-$ .

⇒ Choose signal to include antineutrinos:  
one electron or positron in final state

# Signal definition

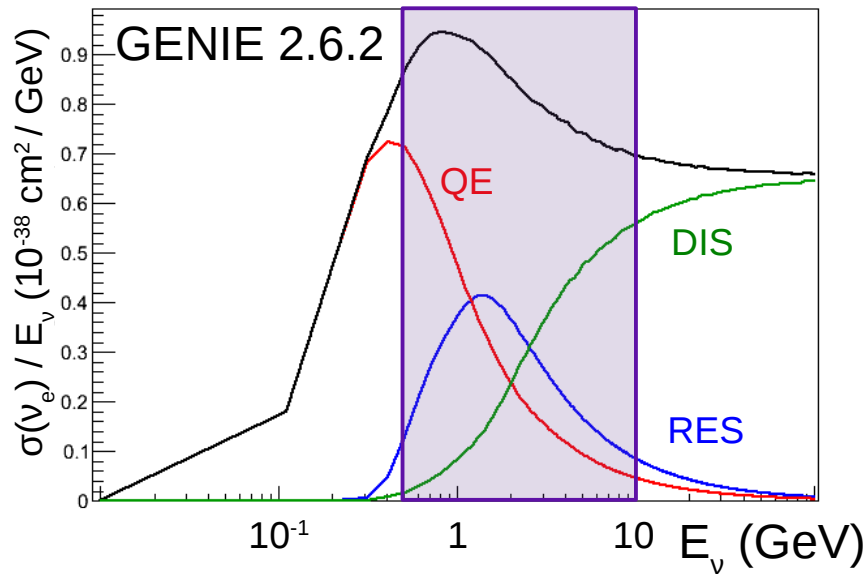

Electron neutrinos from beam muon decay.  
About 10%  $\bar{\nu}_e$ . MINERvA is not magnetized...  
so  $e^+$  looks like  $e^-$ .

⇒ Choose signal to include antineutrinos:  
one electron or positron in final state

Charged-current  $\nu_e$  cross-section per nucleon on  $^{12}\text{C}$

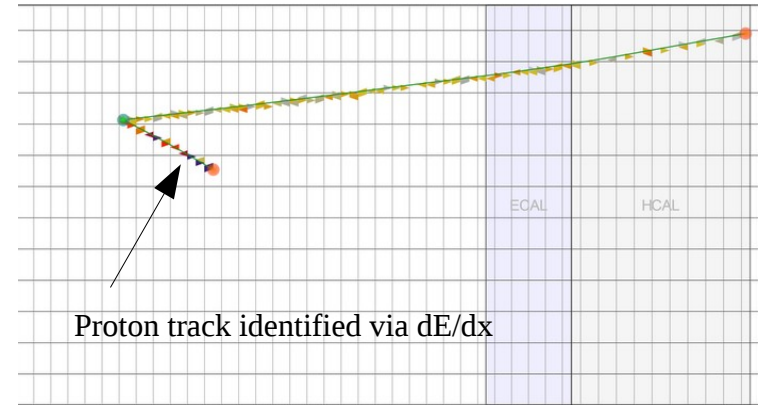

Initial- and final-state effects can cause absorption or creation of hadrons; confusion from DIS (incl. from  $\nu_\mu$  DIS) makes electron ID efficiency lower at moderate energies.

⇒ Choose signal to be *quasielastic-like*:  
any number of nucleons, but no other hadrons allowed in final state

# Constellation of MINERvA CCQE

$\nu_\mu$  "muon + low recoil":  $d\sigma/dQ^2_\mu$   
(see Thursday's talk)

$\nu_\mu$  "muon + proton":  $d\sigma/dQ^2_p$   
(see Thursday's talk)

# Constellation of MINERvA CCQE

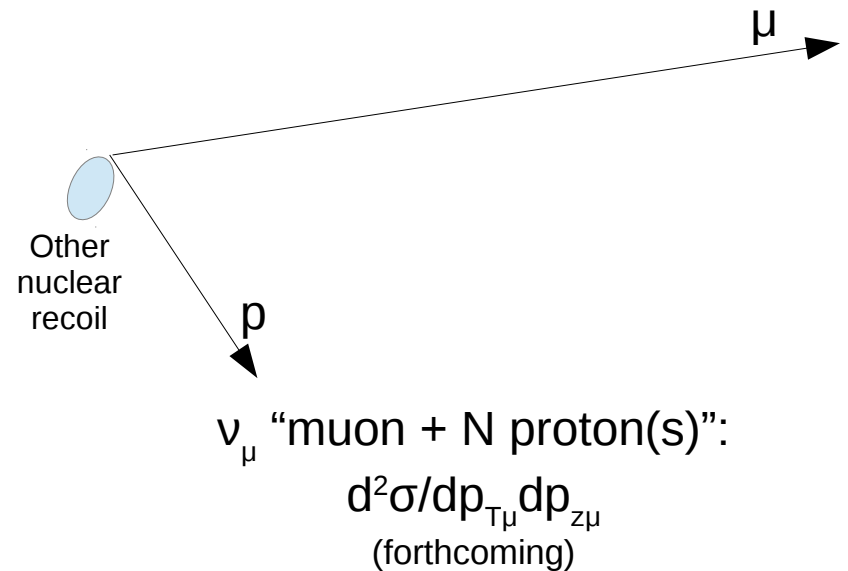

$\nu_\mu$  "muon + low recoil":  $d\sigma/dQ^2_\mu$   
(see Thursday's talk)

$\nu_\mu$  "muon + proton":  $d\sigma/dQ^2_p$   
(see Thursday's talk)

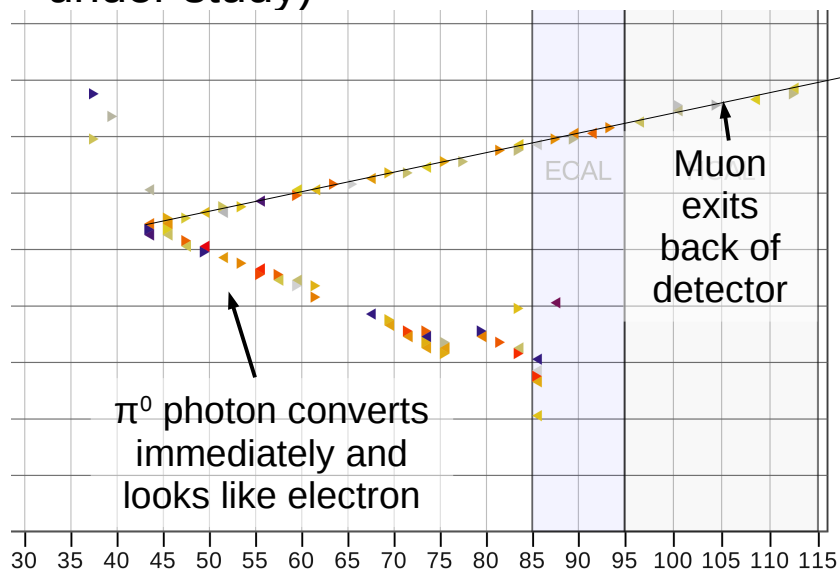

Today's result  
( $\nu_e$  CCQE)  
is most similar  
to this one

# Isolating $\nu_e$ -like events

Event “pre-selection” (EM-enriched):

- One (or more) **reconstructed track(s)** (>85% of  $e^\pm$  in inner detector region begin with track due to low-Z material)
- **No obvious muons** (never  $\nu_e$ ):
  - No tracks exiting back of detector
  - No Michel electron candidates
- Cut on **multivariate PID classifier** combining details of energy profile
- Cut at  $E_e > 1$  GeV for this talk (backgrounds for  $E_e < 1$  GeV still under study)

Simulated background rejected by muon cuts

Event display of simulated  $\sim 4$  GeV  $\nu_e$  interaction in MINERvA

# Isolating $\nu_e$ events: Photon rejection

**The energy deposition pattern early in the track helps discriminate between photons (background) and electrons**

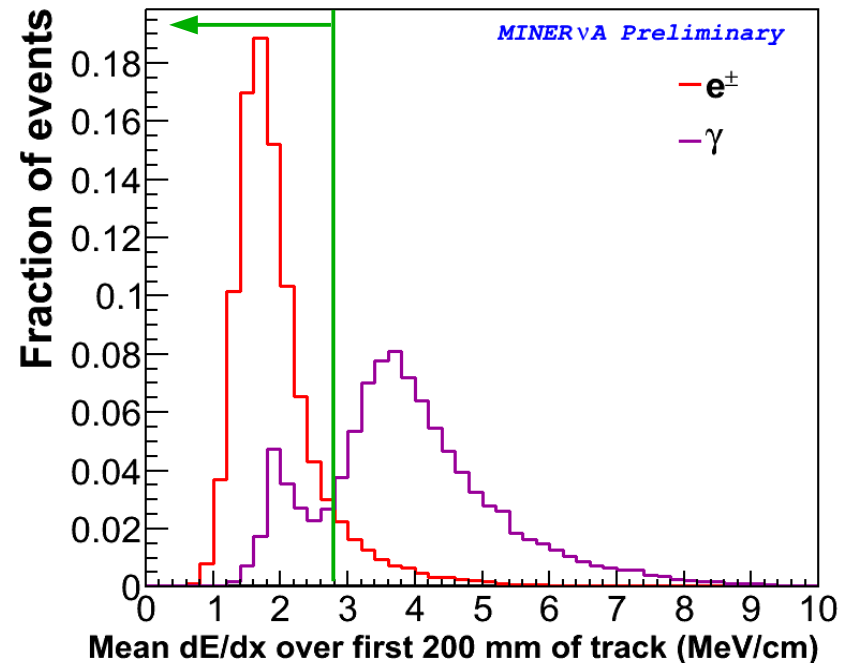

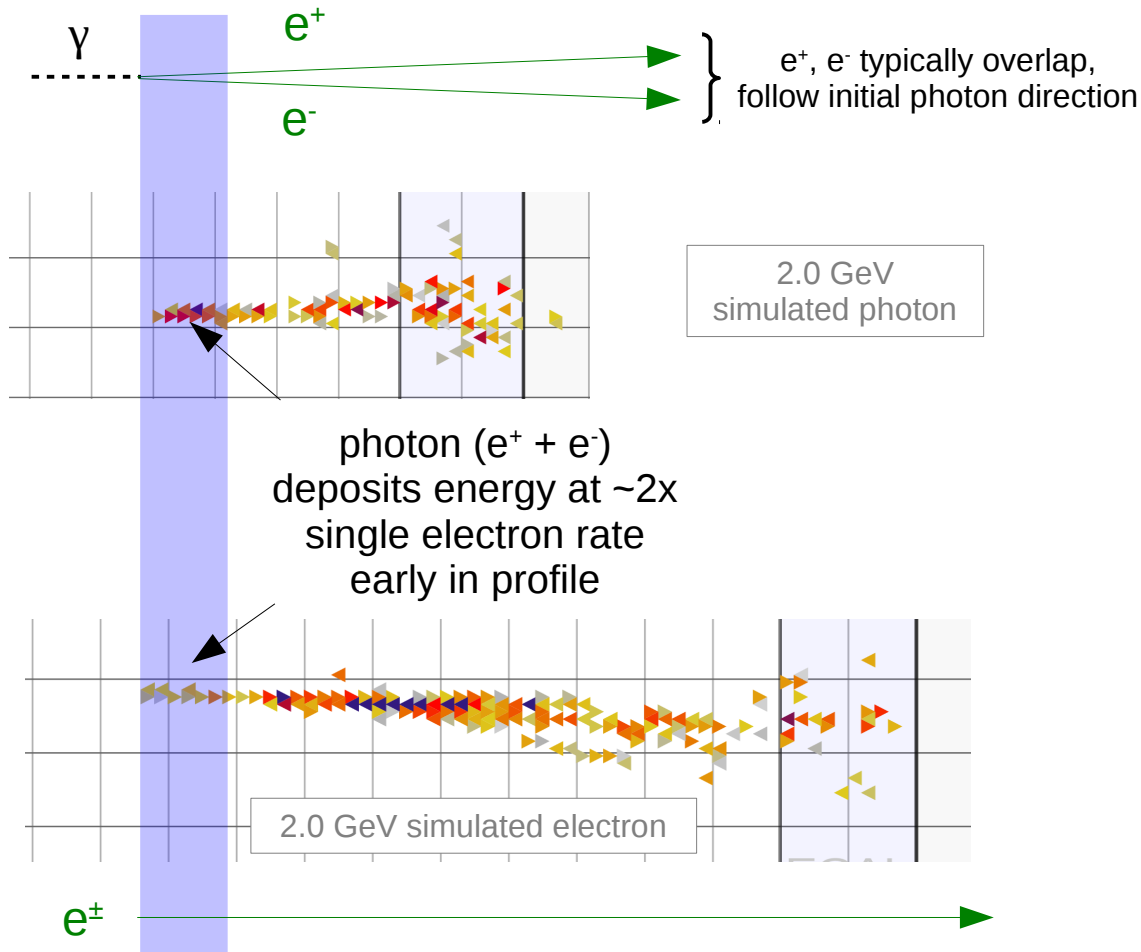

# Isolating $\nu_e$ -like events: Photon rejection

**The energy deposition pattern early in the track helps  
discriminate between photons (background) and electrons**

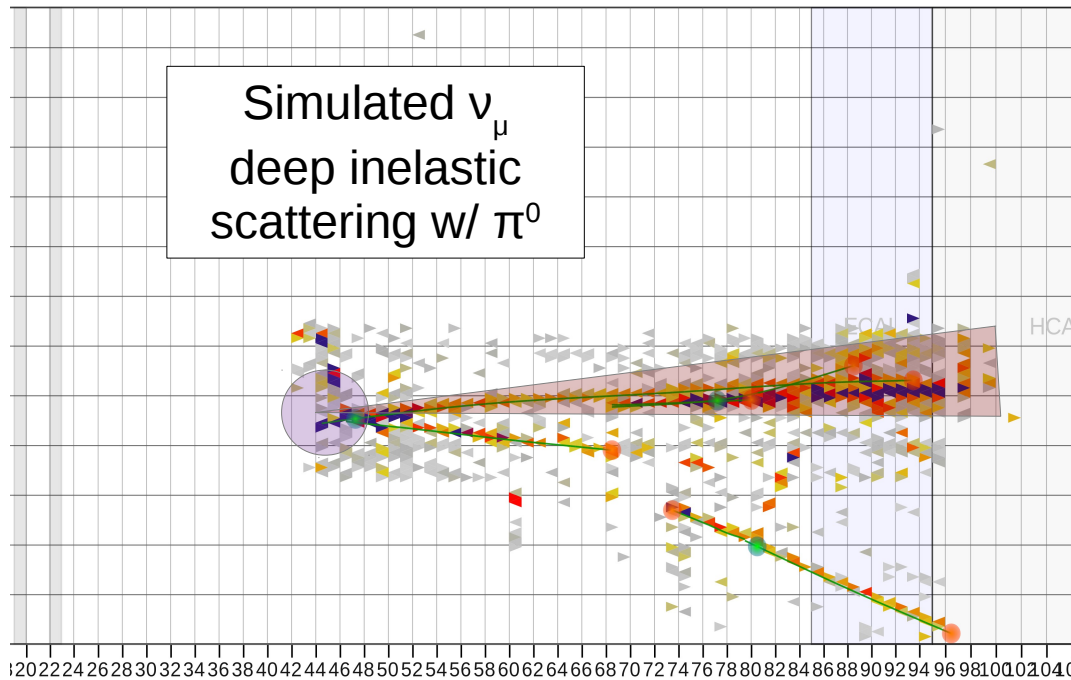

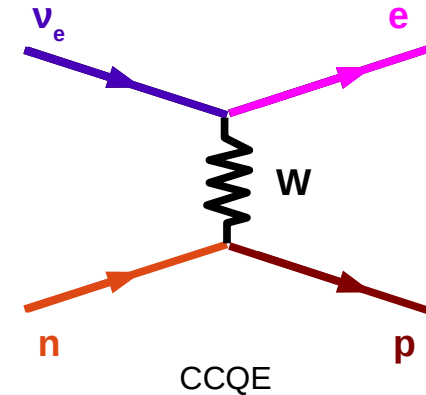

# Isolating $\nu_e$ -like events: Photon rejection

**The energy deposition pattern early in the track helps  
discriminate between photons (background) and electrons**

# Isolating $\nu_e$ -like events: Quasi-elastic-like topology selection

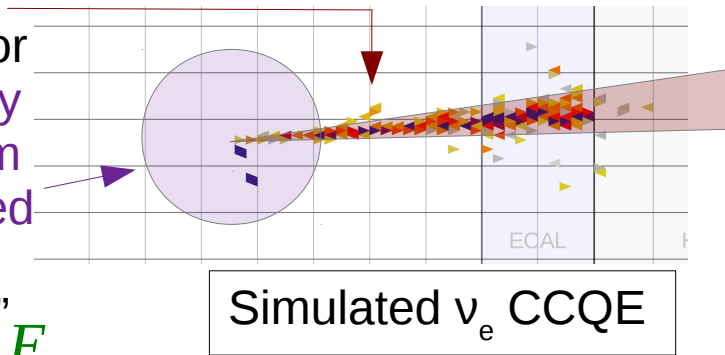

Anything not within a  $7.5^\circ$  electron cone or a vertex activity region of 30 cm radius or tracked as a proton is "extra energy."

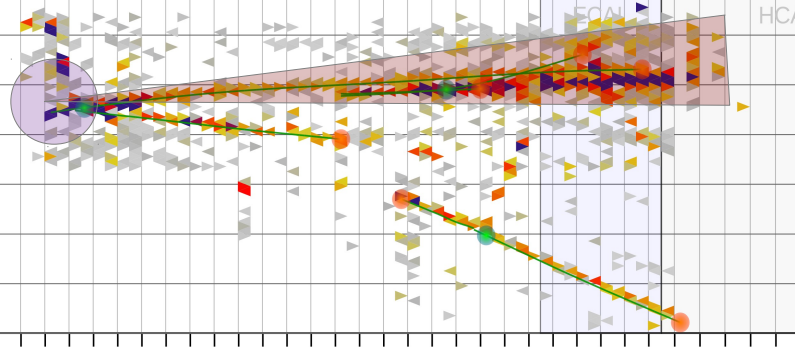

# Isolating $\nu_e$ -like events: Quasi-elastic-like topology selection

Anything not within a  $7.5^\circ$  electron cone or a vertex activity region of 30 cm radius or tracked as a proton is “extra energy.”

Cut on  $\Psi = \frac{E_{extra}}{E_{cone}}$

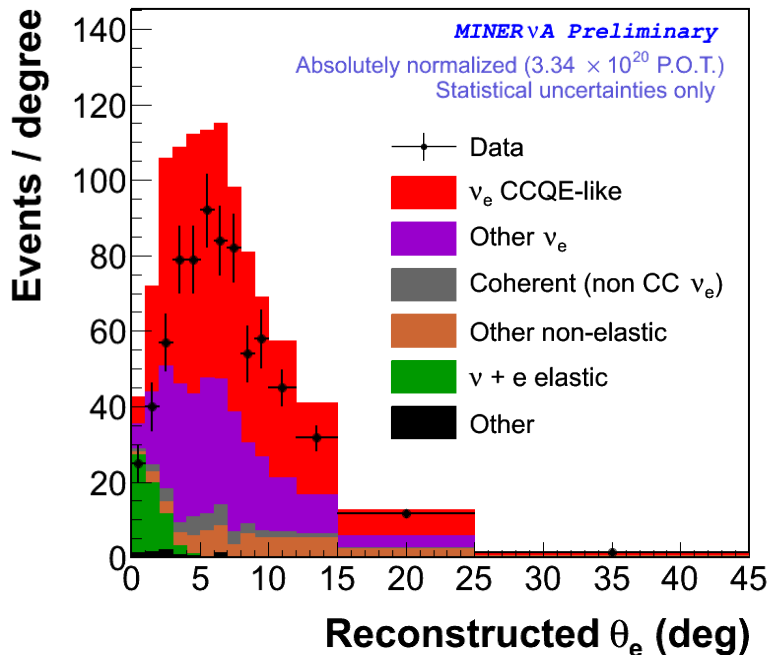

Simulated  $\nu_\mu$  deep inelastic scattering w/  $\pi^0$

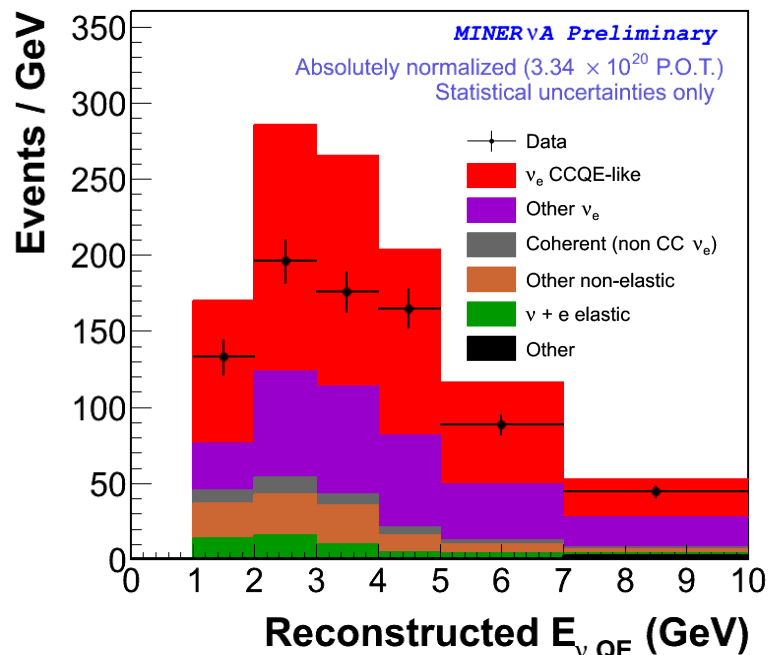

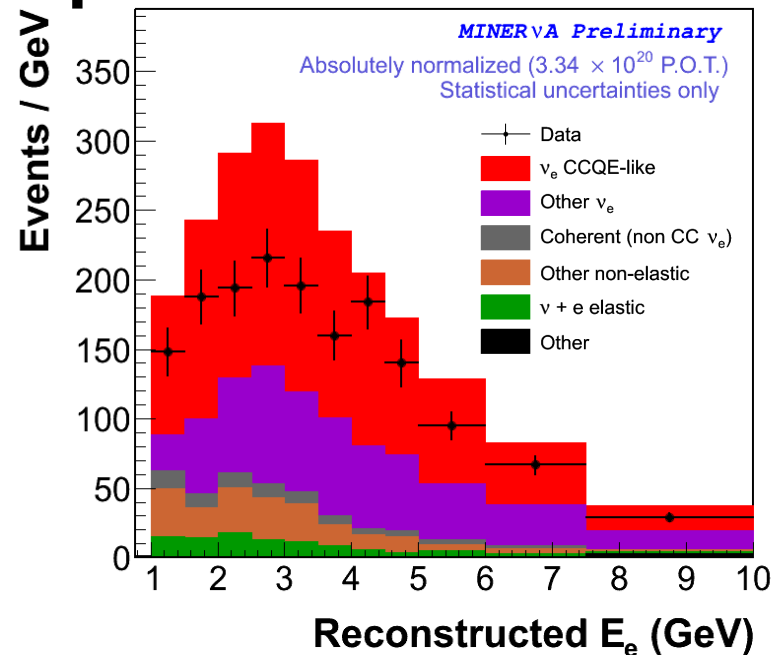

(Actual cut is a function of  $E_{vis}$ .  
Cut illustrated is at most probable value of  $E_{vis} = 0.4$  GeV.)

# Selected sample

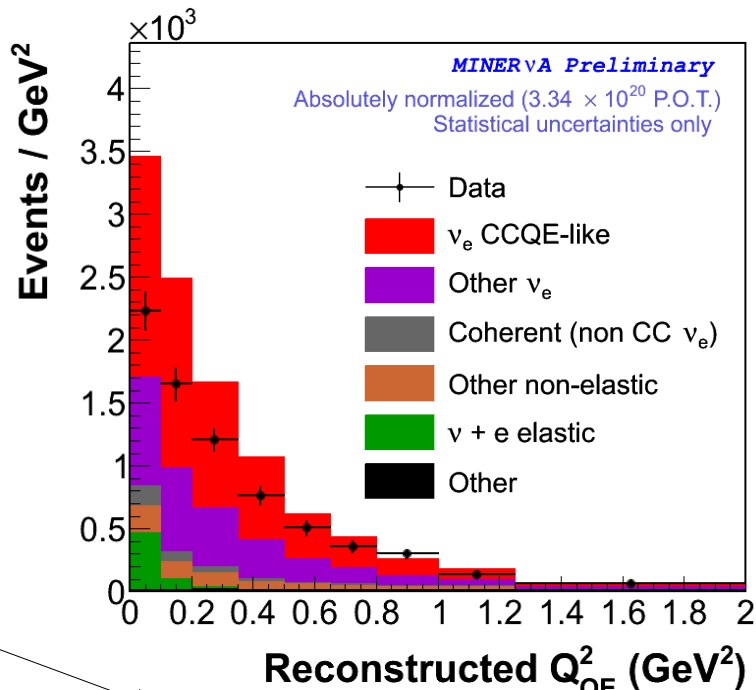

Sample is  
52.1%  $\nu_e$   
CCQE

(83.9%  $\nu_e$   
from any  
channel)

$$E_{\nu}^{QE} = \frac{m_n^2 - (m_p - E_b)^2 - m_{\mu}^2 + 2(m_p - E_b)E_{\mu}}{2(m_p - E_b - E_{\mu} + p_{\mu} \cos \theta_{\mu})}$$

Infer  $\nu$   
kinematics  
from lepton's

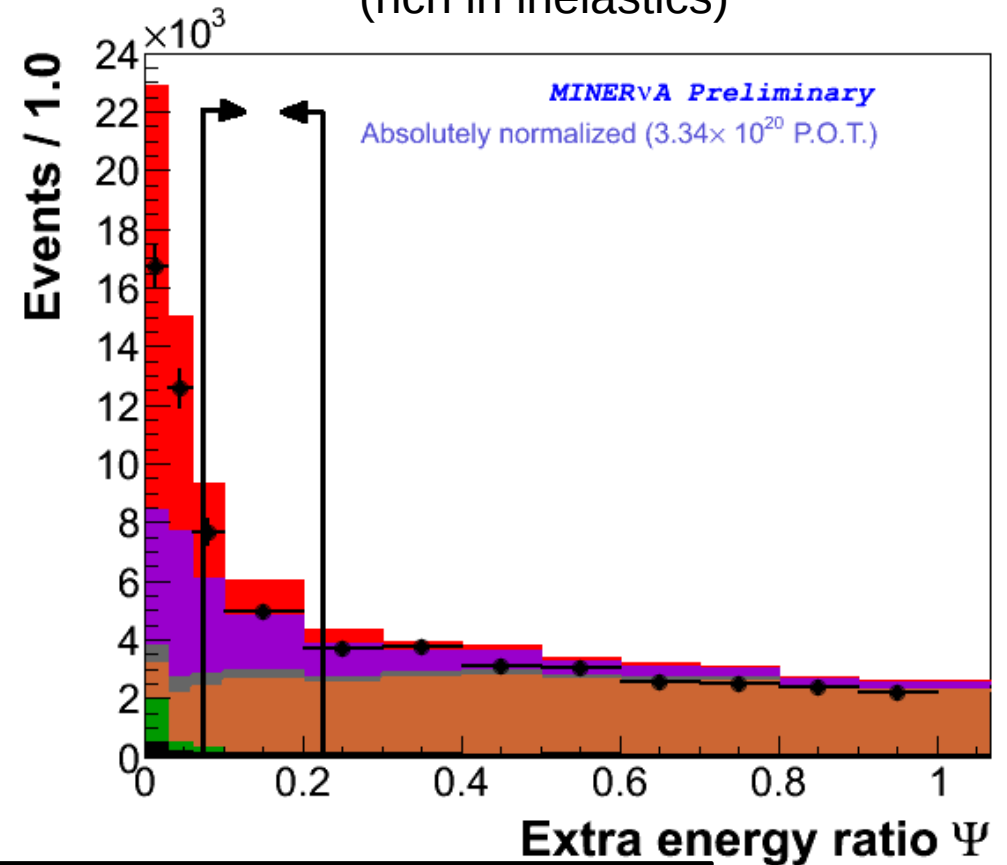

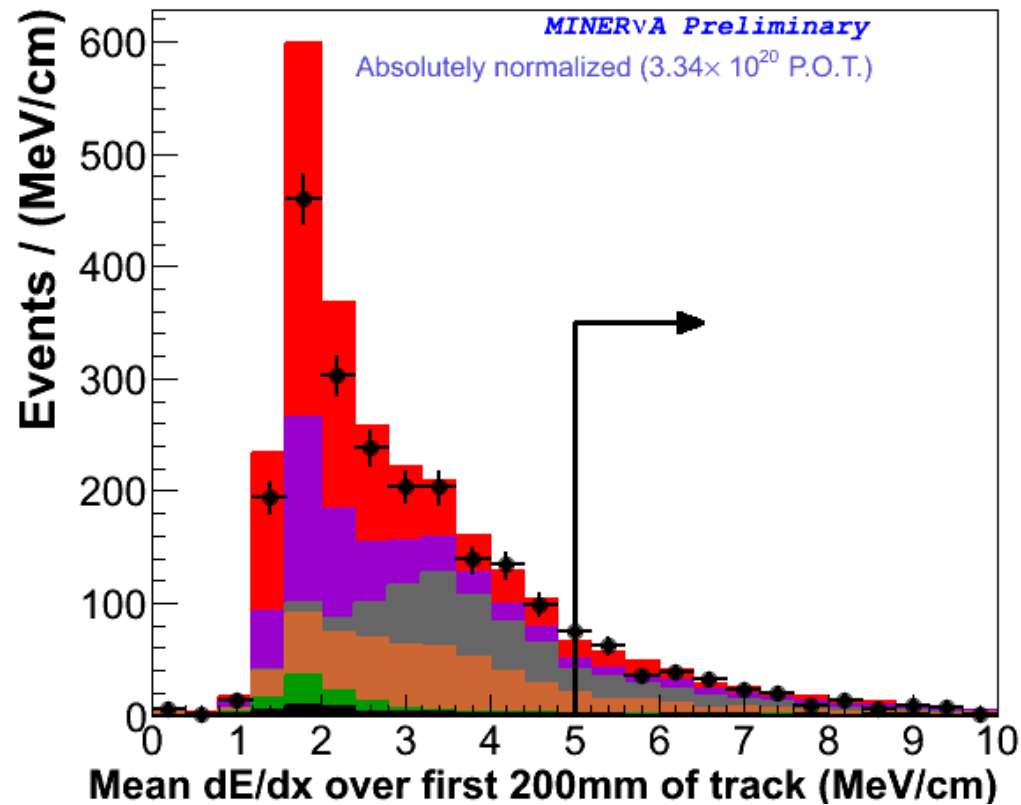

$$Q_{QE}^2 = 2E_{\nu}^{QE}(E_{\mu} - p_{\mu} \cos \theta_{\mu}) - m_{\mu}^2$$

# Constraining backgrounds

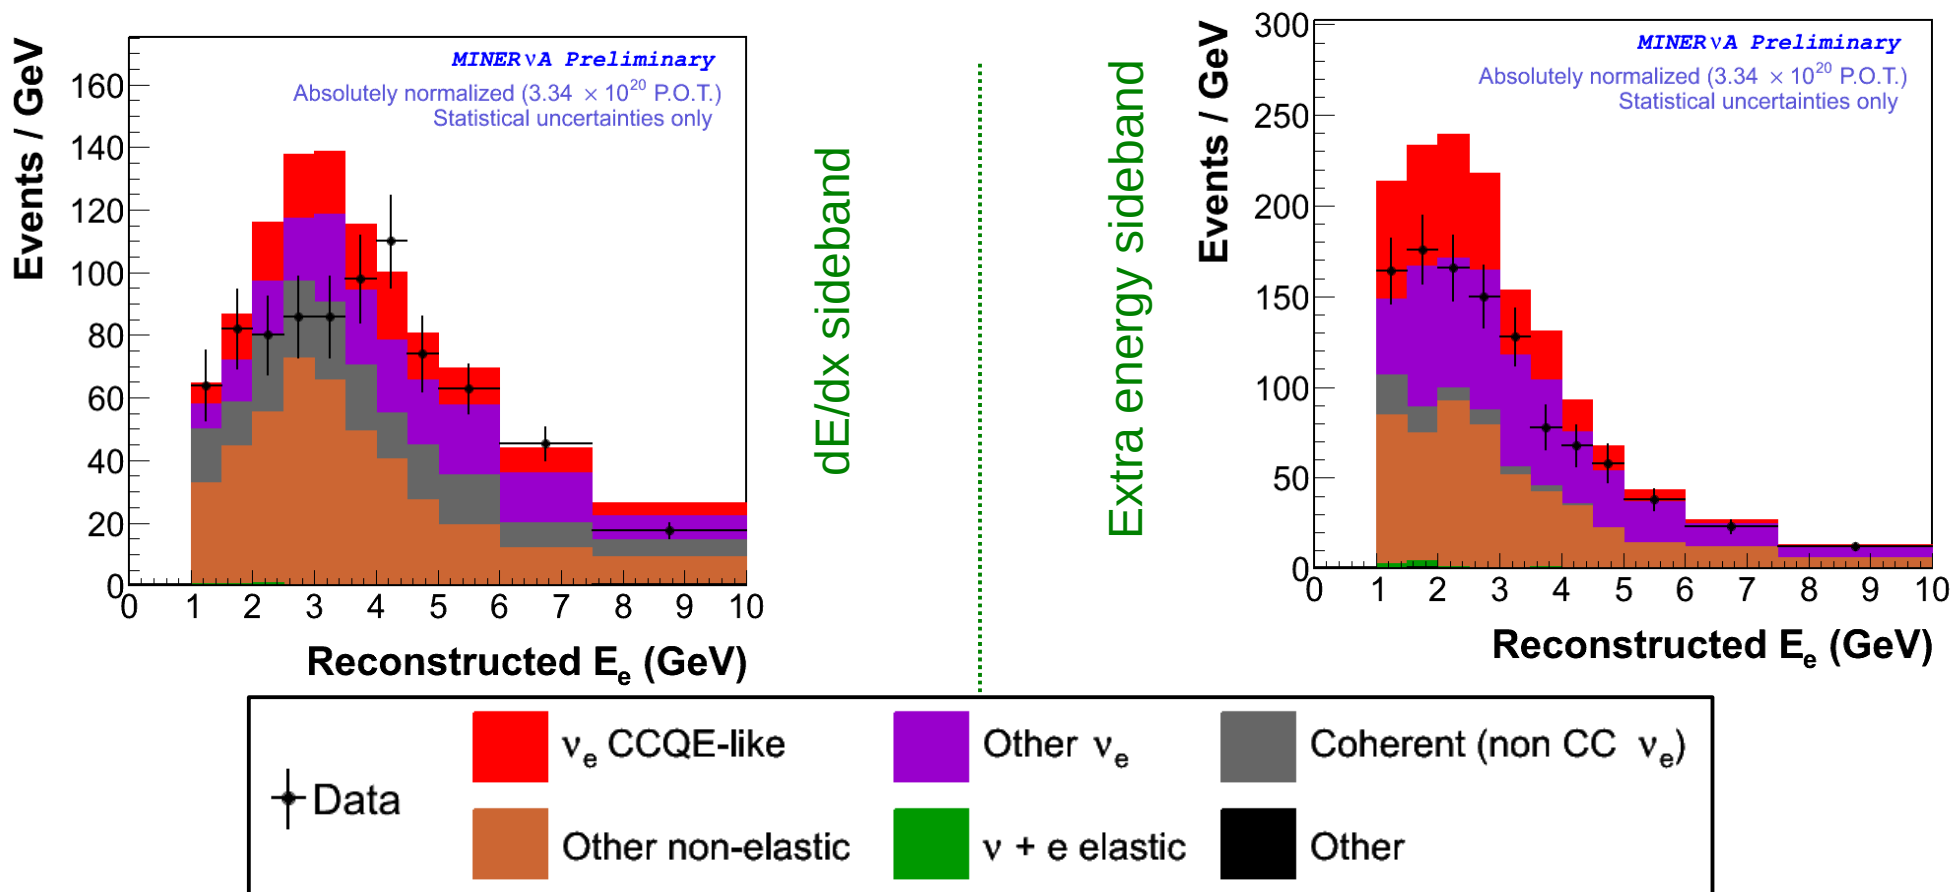

Sideband 1: larger  $dE/dx$   
(photon-rich)

Sideband 2: larger “extra energy”  
(rich in inelastics)

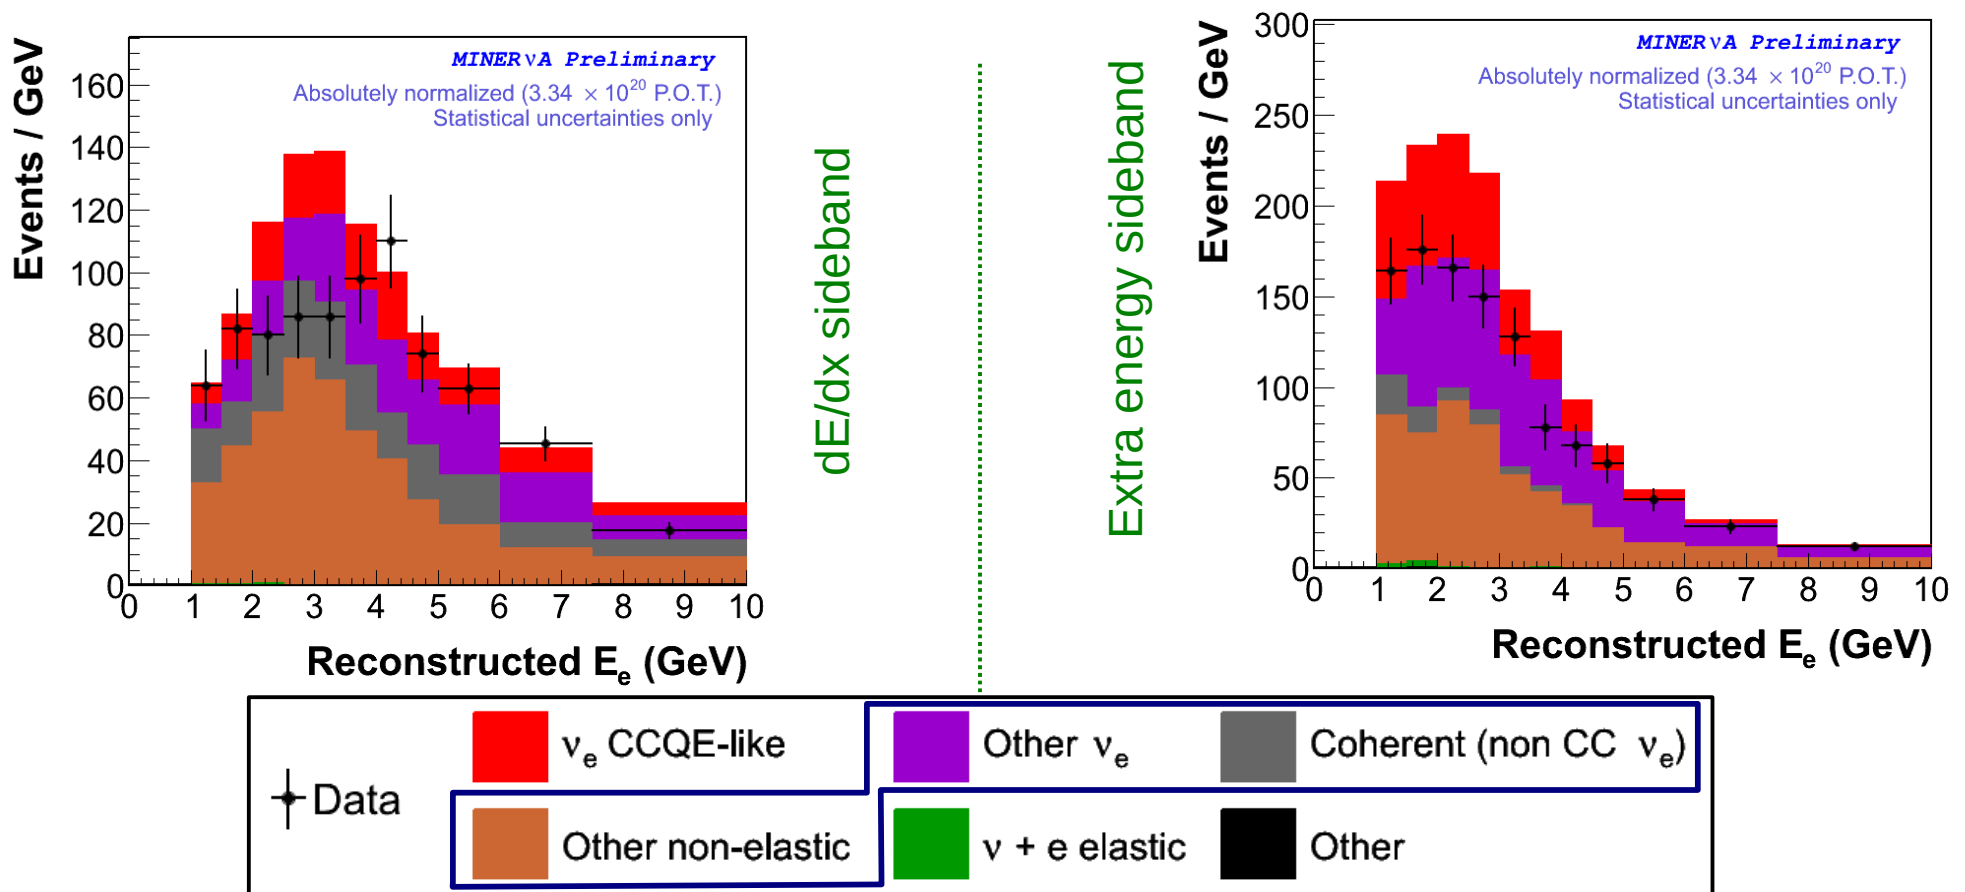

We select two sidebands rich in the major backgrounds...

# Constraining backgrounds

... and examine the normalizations of two distributions in each sideband (one of them, candidate electron energy, shown here; we also use candidate electron angle).

# Constraining backgrounds

... and examine the normalizations of two distributions in each sideband (one of them, candidate electron energy, shown here; we also use candidate electron angle).

We fit the normalizations of the “other  $\nu_e$ ,” “coherent,” and “other non-elastic categories” together, using the four distributions simultaneously.

# Constraining backgrounds

This is one of four (sideband, variable) combinations that are fitted simultaneously.

The fitted scale factor is 0.69 (same trend as inelastics in other MINERvA analyses)

# Steps to a cross-section

$$\left(\frac{d\sigma}{dE_e}\right)_i = \frac{1}{\Phi} \times \frac{1}{T_n} \times \frac{1}{(\Delta E_e)_i} \times \frac{\sum_j U_{ij} (N_j^{data} - N_j^{bknd})}{\epsilon_i}$$

(number of targets)      (bin width)      (unsmearing matrix)      (efficiency)

# Steps to a cross-section

$$\left(\frac{d\sigma}{dE_e}\right)_i = \frac{1}{\Phi} \times \frac{1}{T_n} \times \frac{1}{(\Delta E_e)_i} \times \frac{\sum_j U_{ij} (N_j^{data} - N_j^{bknd})}{\epsilon_i}$$

(unsmearing matrix)

(efficiency)

Flux (number of targets) (bin width)

We constrain the flux using a separate *in situ* measurement of the neutrino-electron elastic scattering rate (also constrains this background)

J. Park, FNAL JETP seminar, 20 Dec 2013

## Flux constraining using nu-e (spectrum)

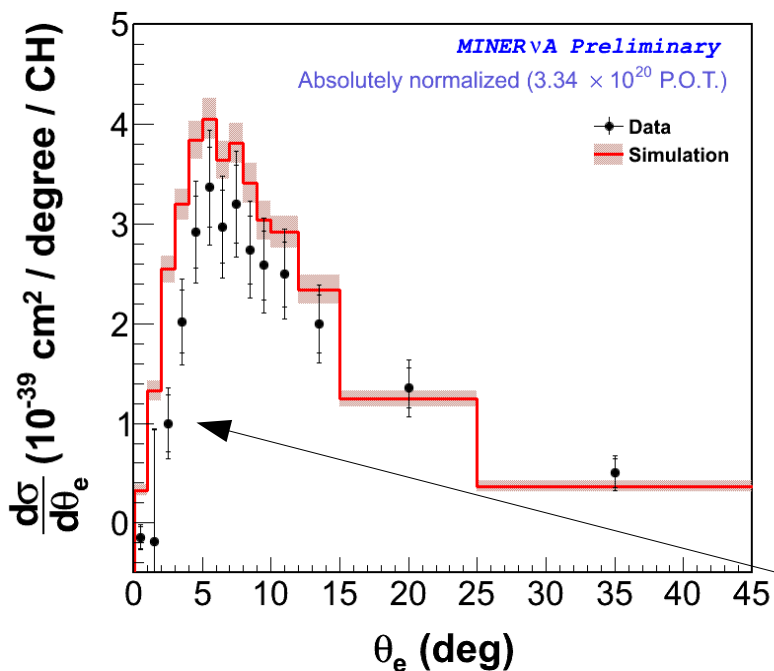

# Uncertainty summary

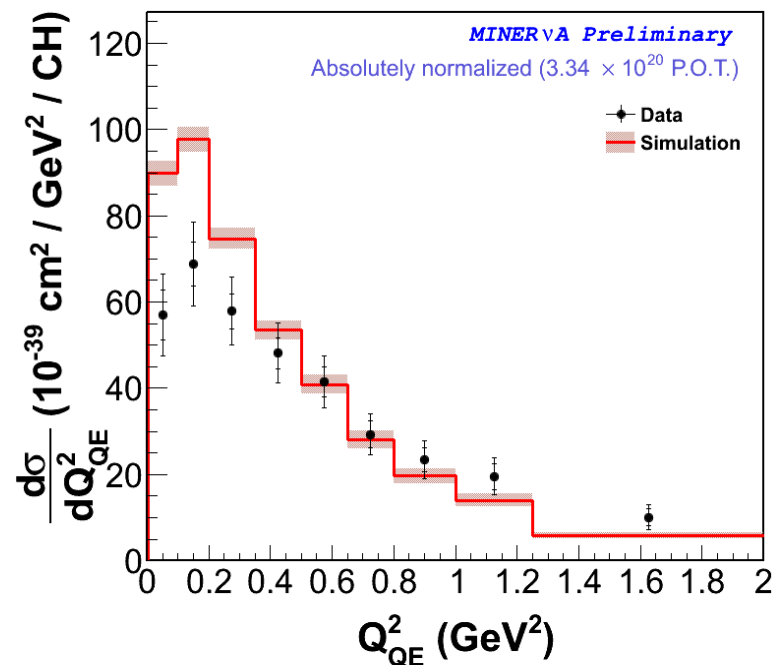

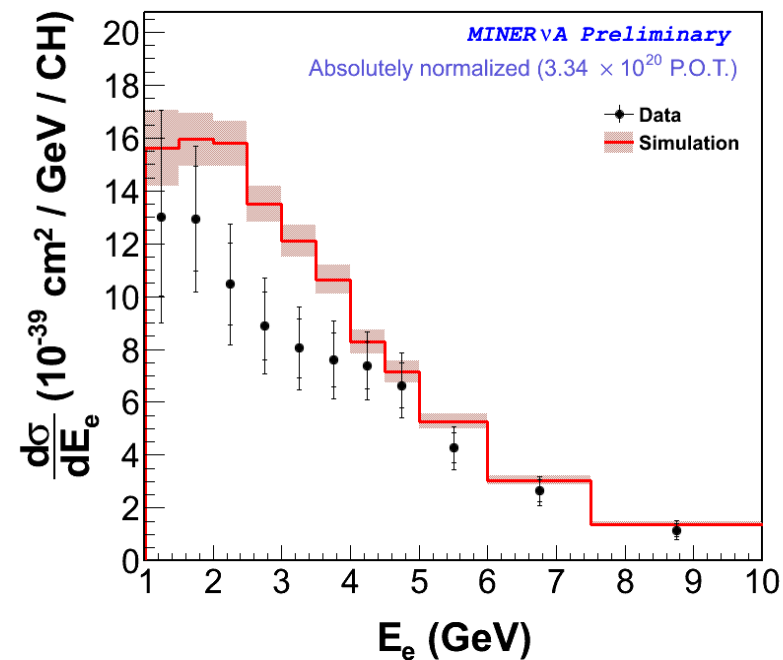

Uncertainties due to the GENIE interaction model and the statistics are roughly comparable

# Cross-sections

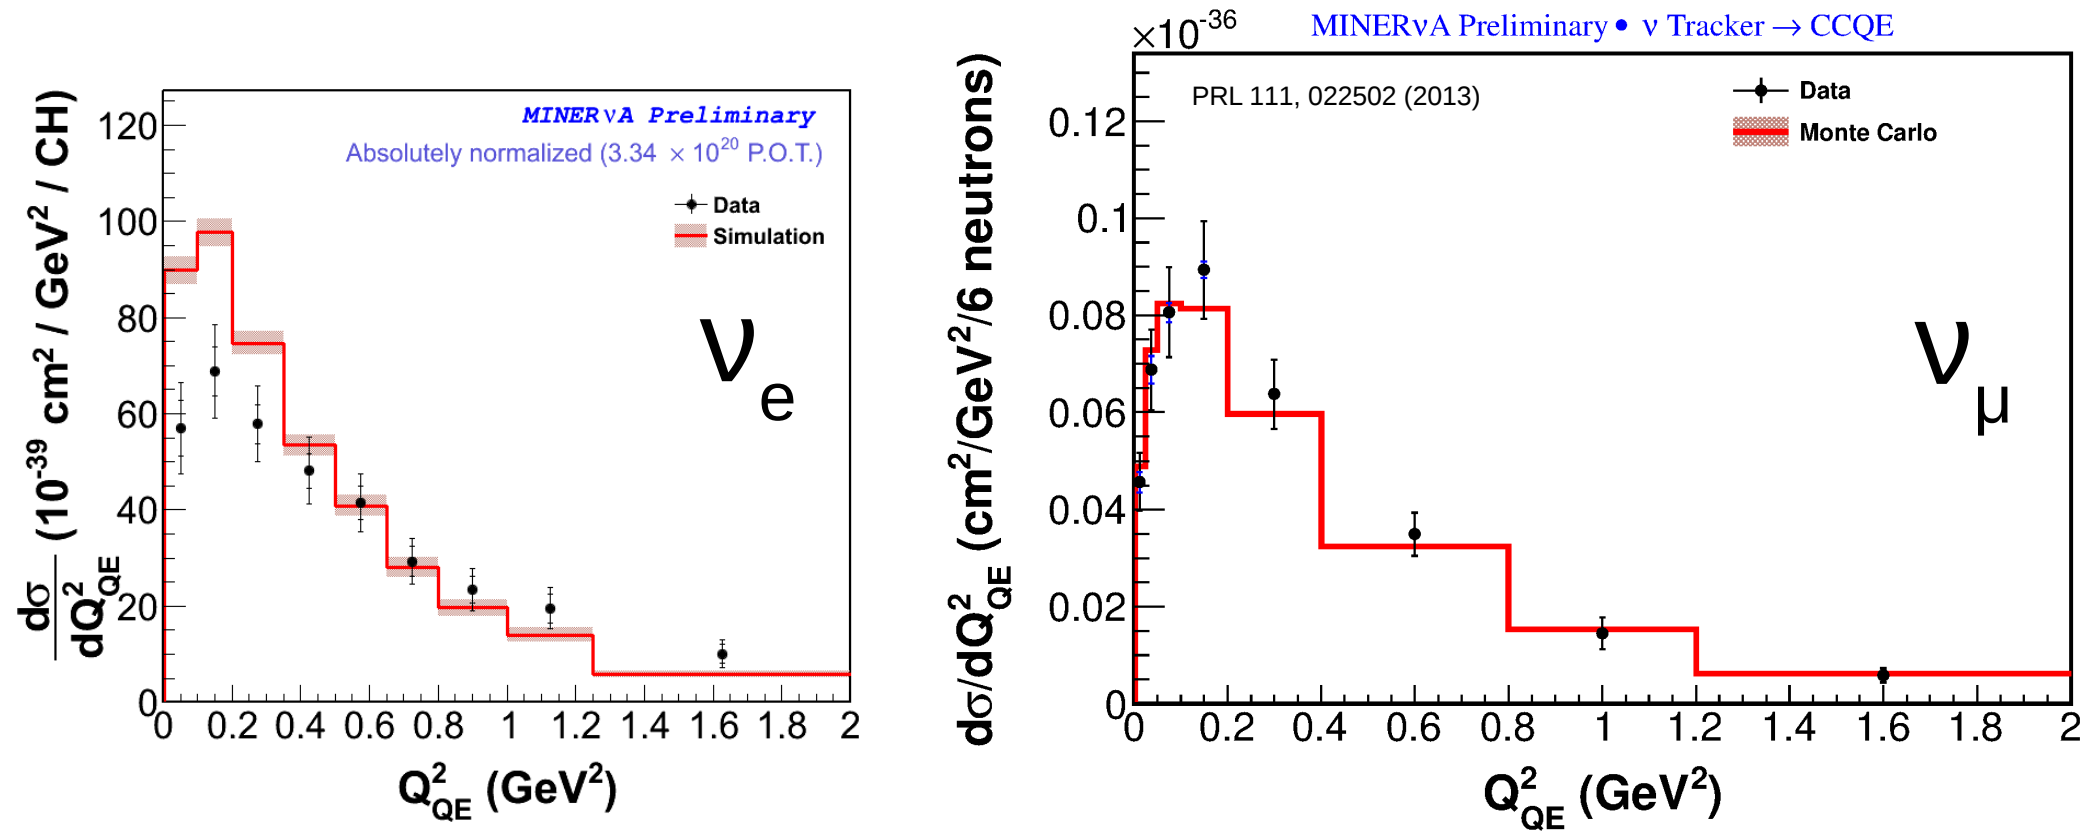

Observation

The simulation (GENIE 2.6.2) overpredicts the rate at low angles!

# Comparison to $\nu_\mu$

## Observations

- GENIE  $\nu_e$  prediction is larger in normalization than  $\nu_\mu$ , while data trend is opposite
- Data  $\nu_e$  spectrum is harder than  $\nu_\mu$  in  $Q^2$

# Summary and outlook

- $\nu_e$  cross-sections are important for oscillation expts.
- We observe a discrepancy at low angles between GENIE 2.6.2 and our data in  $d\sigma/d\theta_e$
- The  $Q^2$  spectrum appears to be harder for  $\nu_e$  CCQE than for  $\nu_\mu$  CCQE
- Work is ongoing to characterize the backgrounds in the  $E_e < 1$  GeV region
- Further study of systematics is ongoing

Thanks for your attention!

# Isolating $\nu_e$ -like events:

## EM-like final state selection

1. What fraction of energy is deposited at the track end?

3. What is the track's mean  $dE/dx$ ?

We train a multivariate classifier using these three characteristics of the energy deposition profile of the shower-like object

# Isolating $\nu_e$ -like events:

## EM-like final state selection

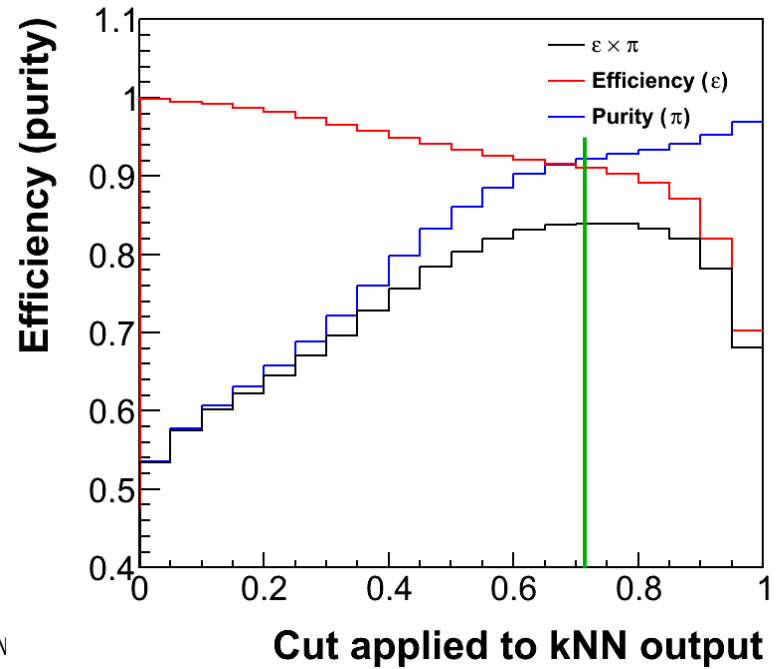

1. What fraction of energy is deposited at the track end?

2. How "wide" is the track?

3. What is the track's mean  $dE/dx$ ?

We train a multivariate classifier using these three characteristics of the energy deposition profile of the shower-like object

# PID variable: endpoint energy fraction

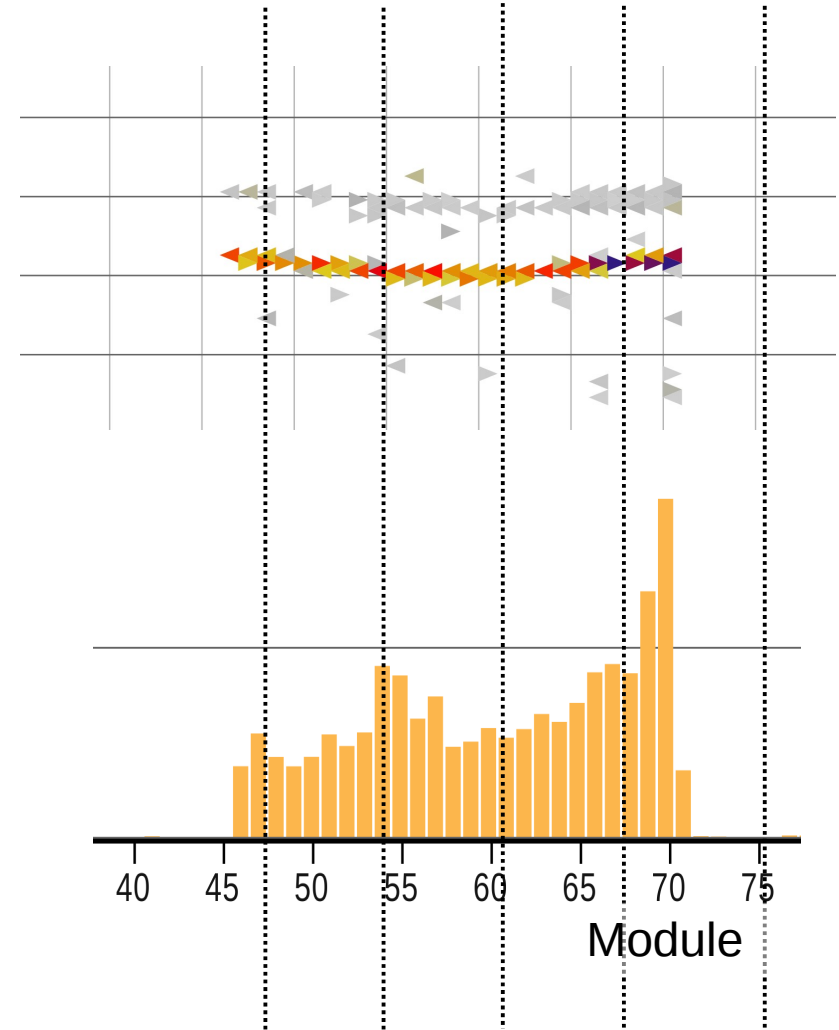

5.6 GeV e<sup>-</sup>

470 MeV p<sup>+</sup>

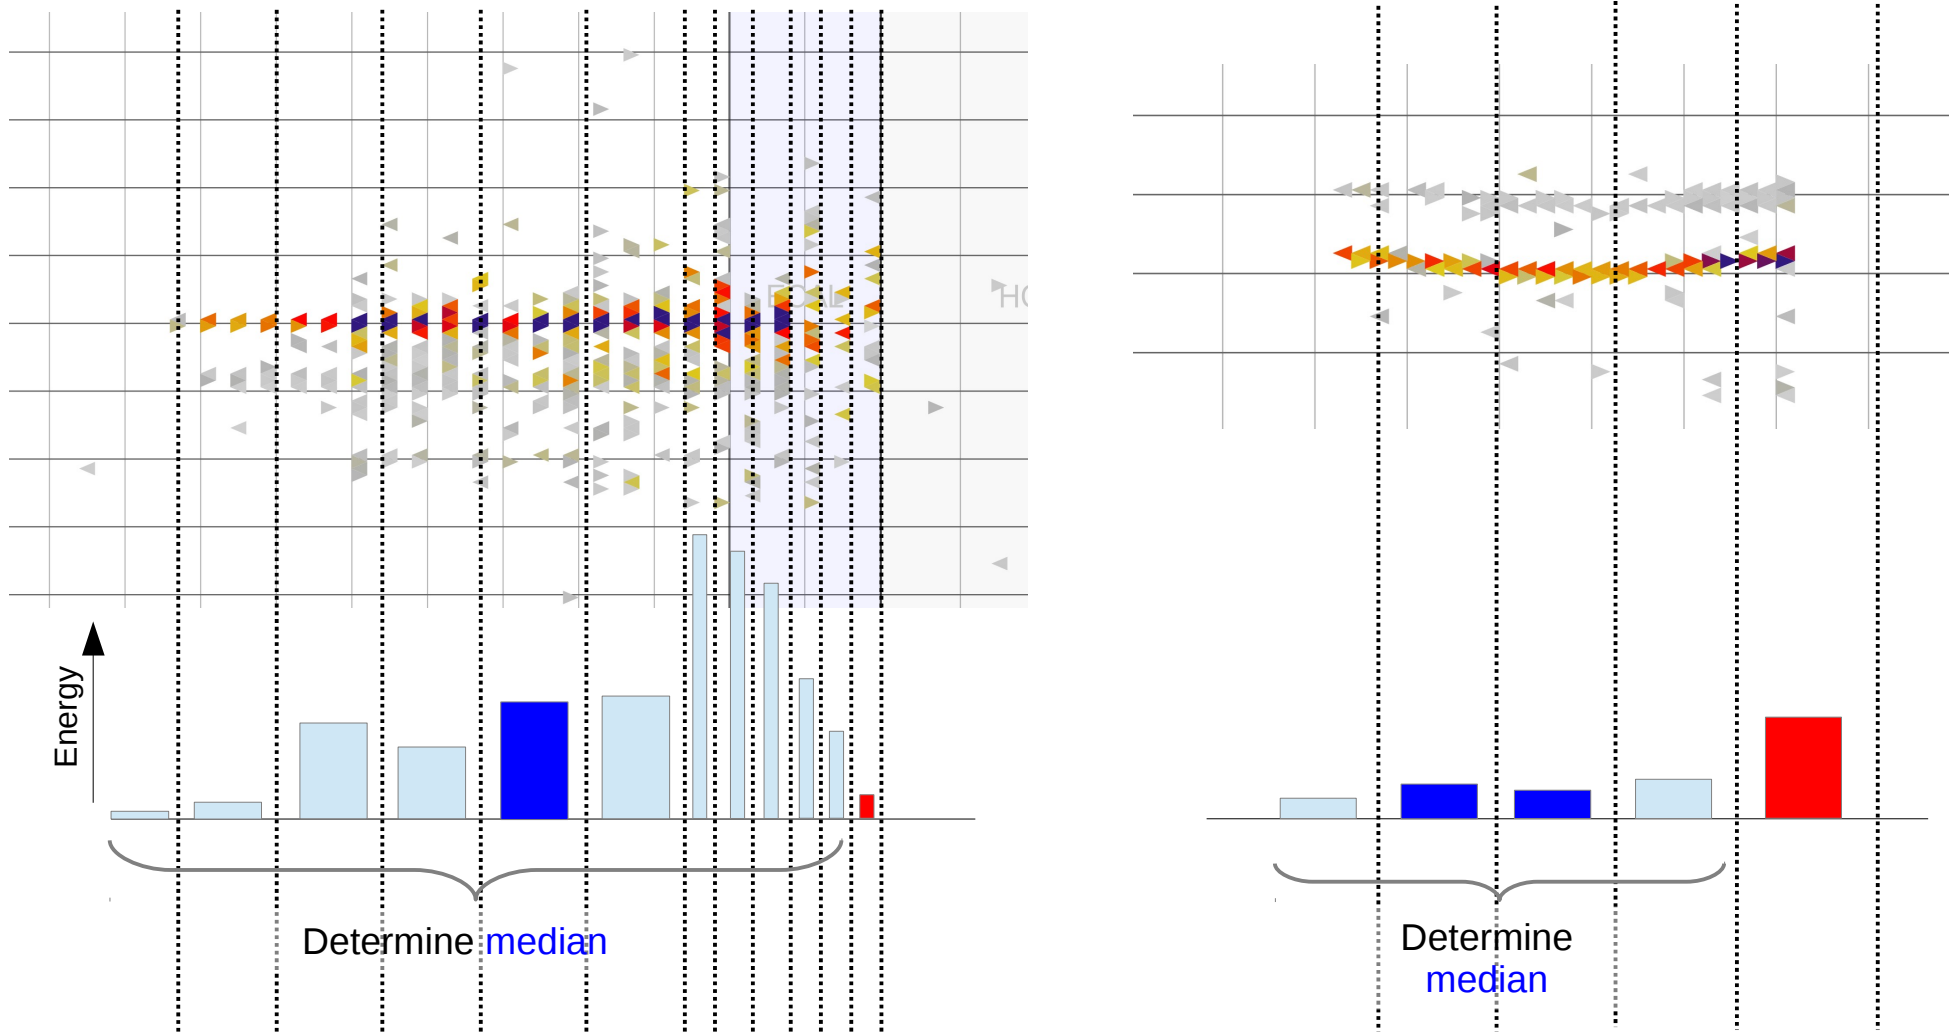

# PID variable: endpoint energy fraction

1. Divide the energy deposits into bins of  $10 \text{ g/cm}^2$  of areal density.

# PID variable: endpoint energy fraction

2. Correct the energy deposits for the calorimetry.
3. Determine the **median** of the energy deposits (excluding the **last one**).

# PID variable: endpoint energy fraction

5.6 GeV e-

4. Endpoint energy fraction =  $\frac{E_{last}}{E_{median}}$

# PID variable: shower “width”

Merge MIP-like pairs like this one (two brightest strips are neighbors) into one pseudo-strip with the sum of their charge

# PID variable: shower “width”

strip  
number

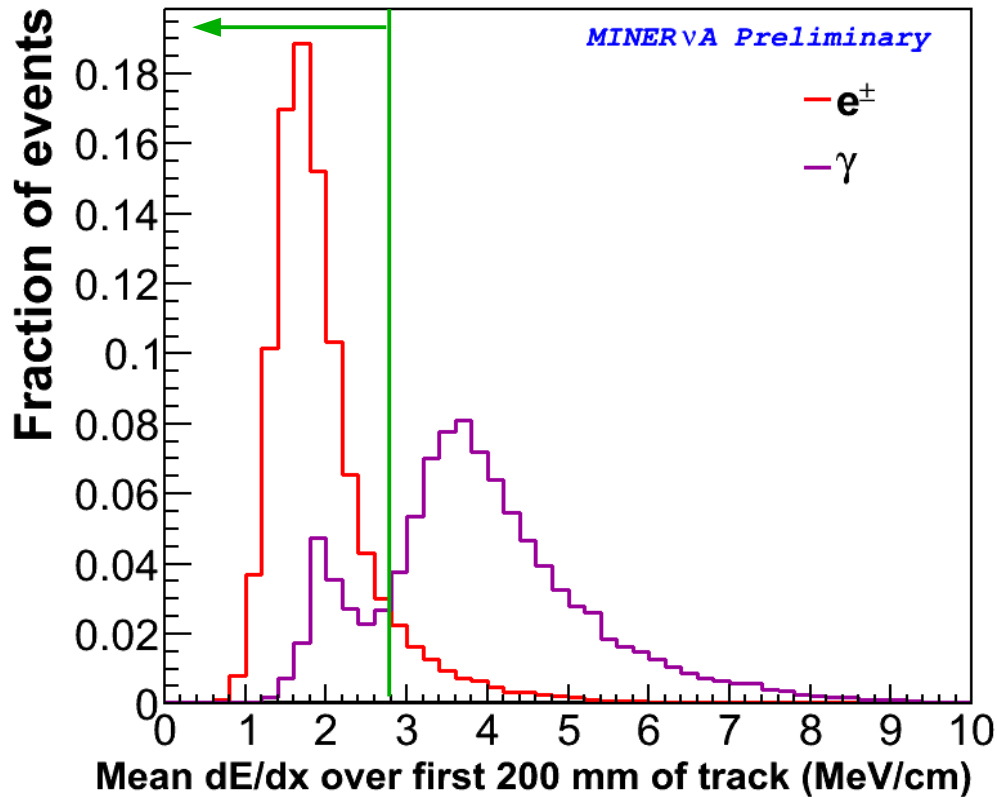

Take standard deviation of illuminated strip numbers (after merging), weighted by charge, in this plane

For each plane:

Then use the median of those standard deviations to characterize the event's “width”

# Photon rejection cut

# “Extra energy” cut

Anything not within a  $7.5^\circ$  electron cone or a vertex activity region of 30 cm radius or tracked as a proton is “extra energy.”

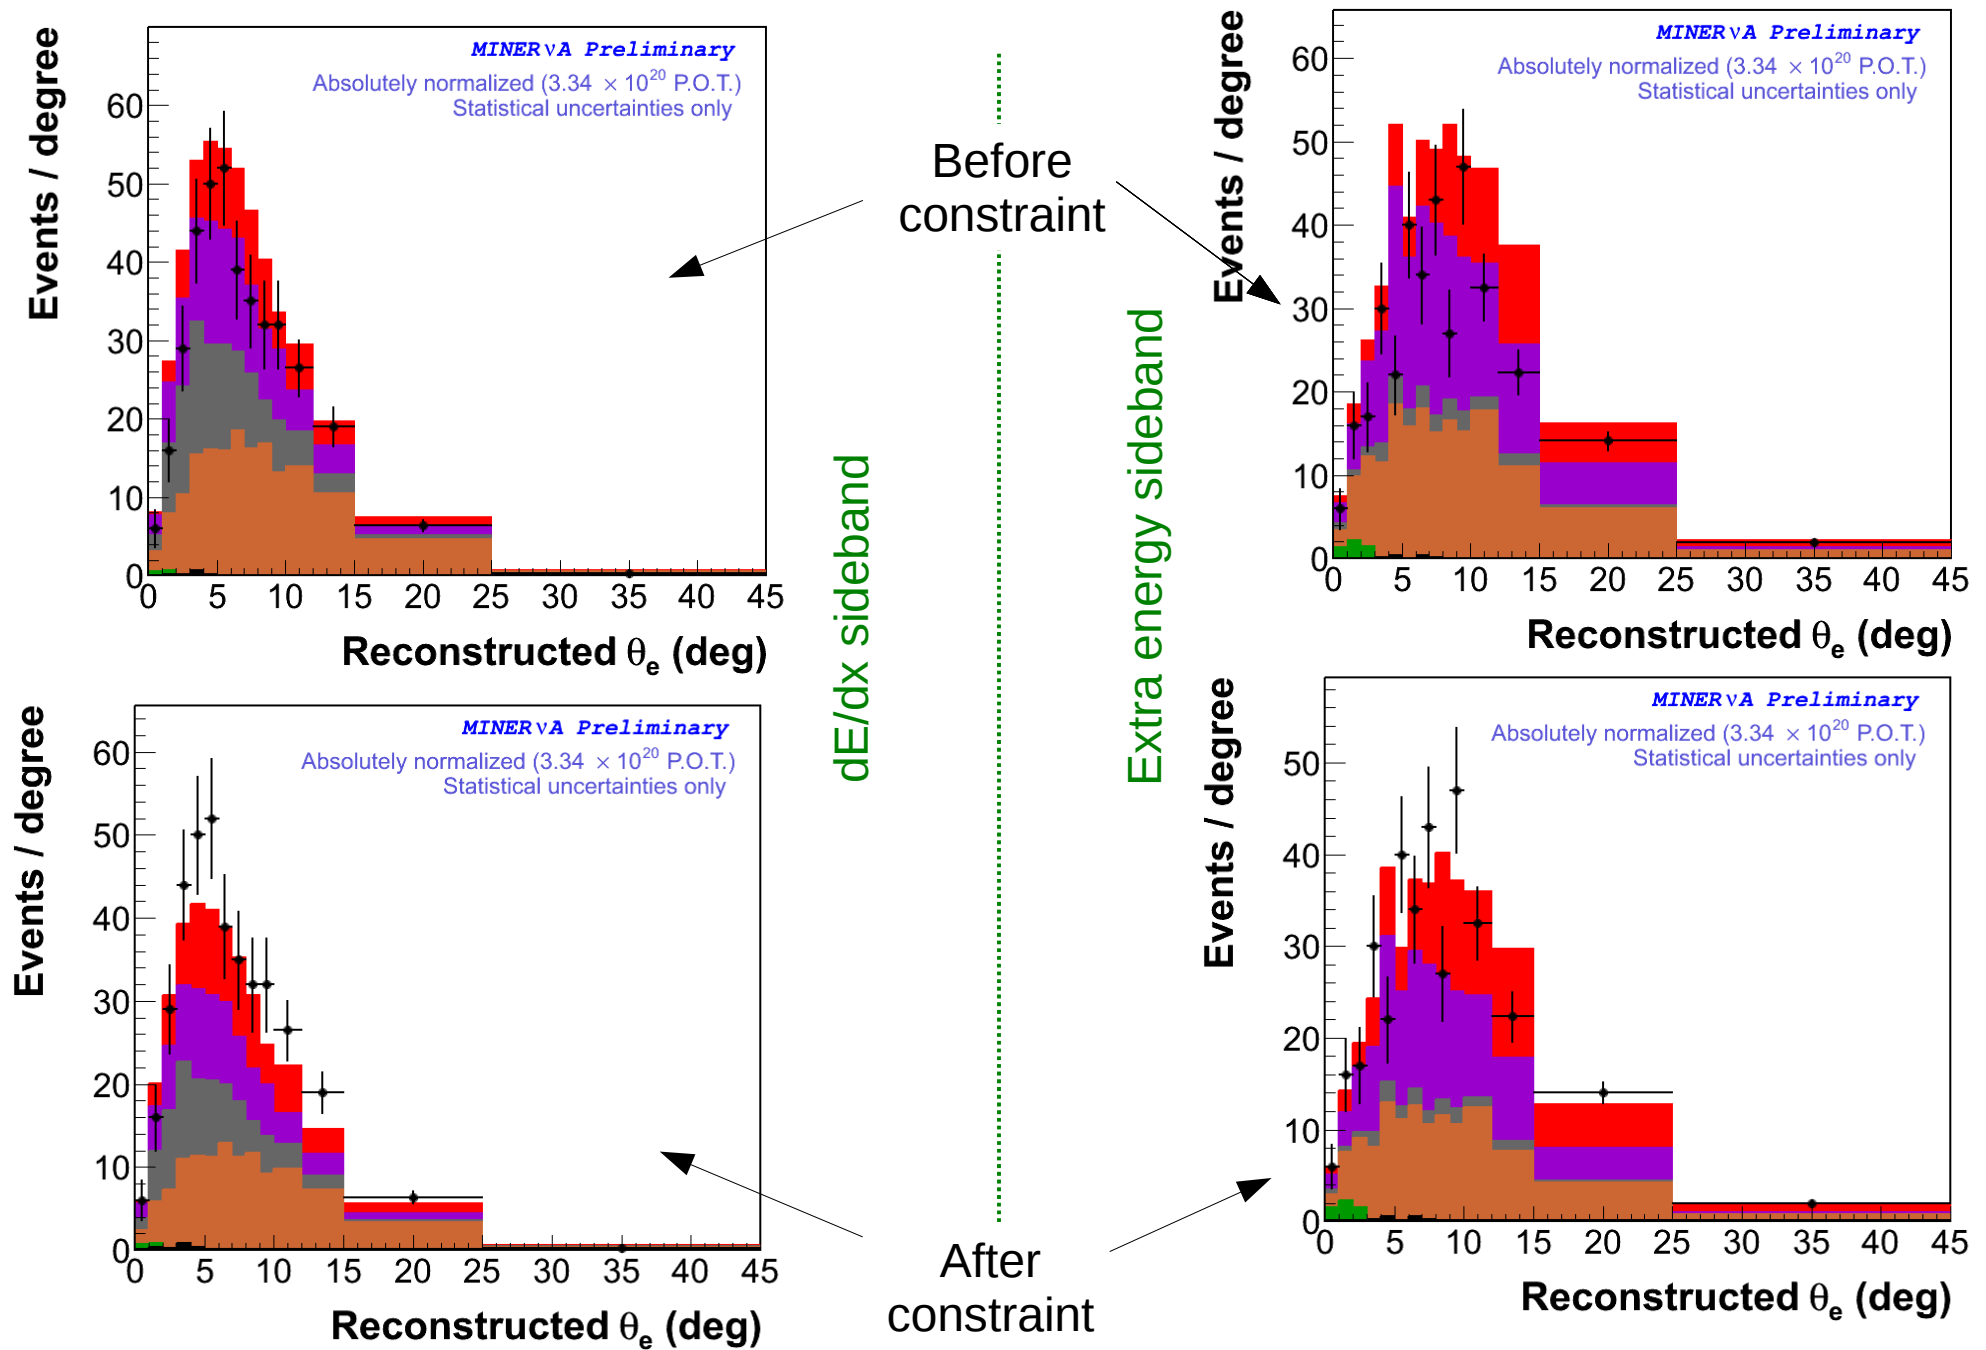

Cut on  $\Psi = \frac{E_{extra}}{E_{cone}}$

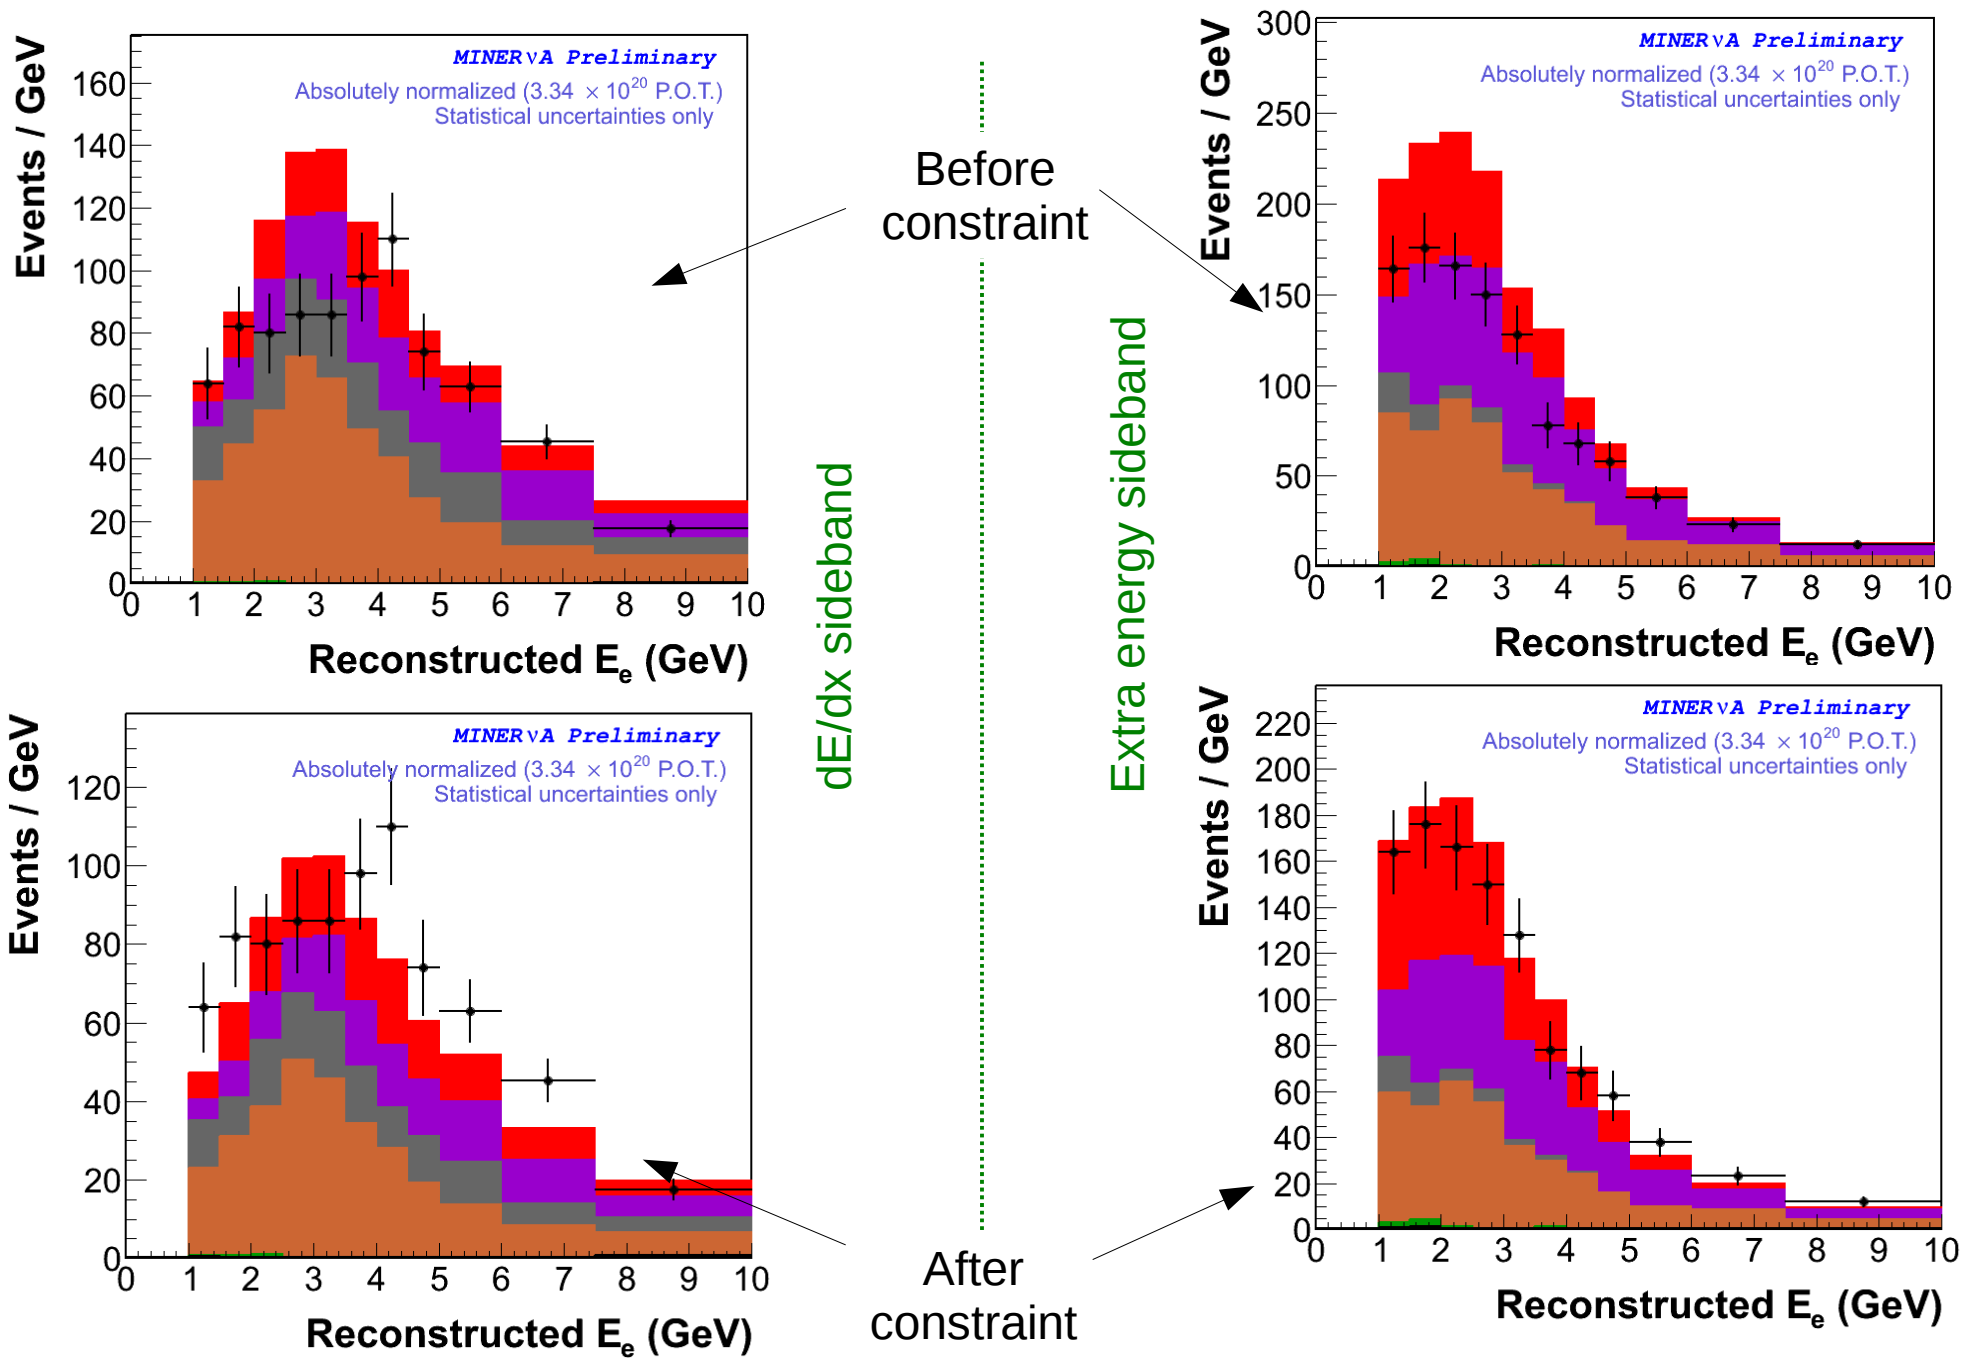

After marginalizing over all  $E_{vis}$ , Cut illustrated is at most probable value of  $E_{vis} = 0.4$  GeV.

# Background constraint: $\theta_e$

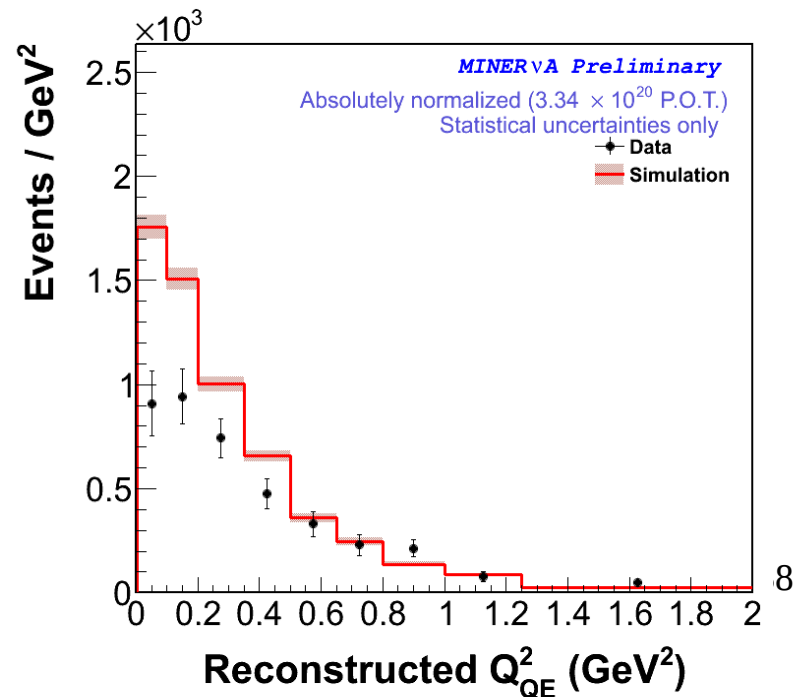

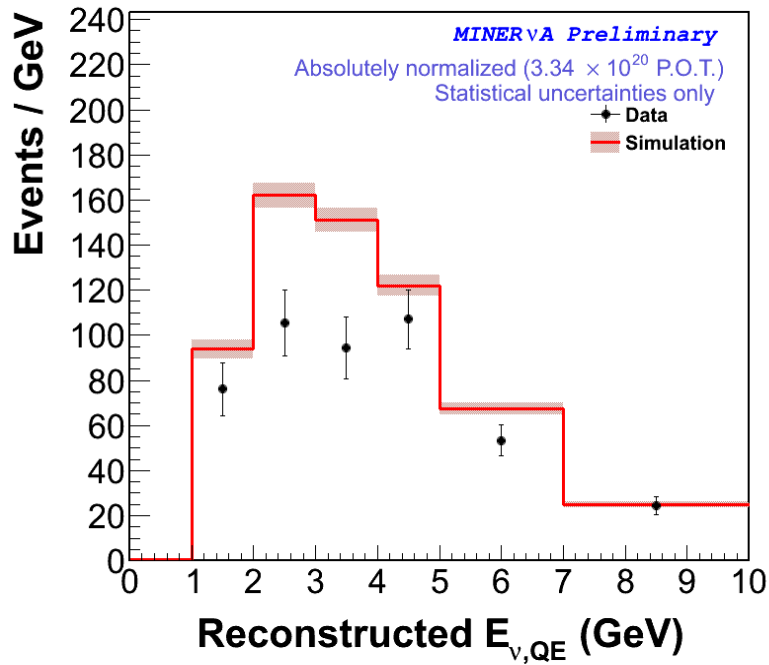

# Background constraint: $E_e$

# Background-subtracted distributions

Notice the model's excess in the forward region...

# Unfolded distributions

We use *one* iteration of a Bayesian unfolding technique.

# Efficiency

Mean  
selection  
efficiency  
is 30.9%.

# Constrained flux prediction

Reduction of 5-10% in prediction,  
and 5-10 percentage points in predicted uncertainty as well

# Data/MC ratios

# Non-flux uncertainties

1.8% EM energy scale uncertainty from fitting  $\pi^0$  mass peak

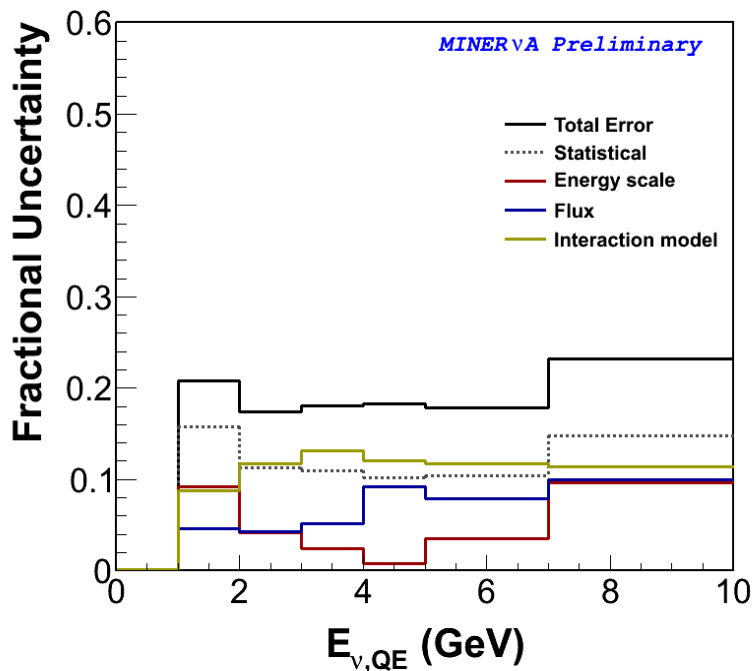

GENIE generator uncertainties are dominated by uncertainties on inelastic pion interactions and pion absorption in final-state interaction model (both of which affect the  $\pi^0$  content of the background prediction and the prediction of the signal within the sidebands)

# Cross-section uncertainties

The GENIE interaction model and statistics are comparable in most cases (depending on binning)

# Cross-section uncertainties
