

Multidimensional analysis of Bose-Einstein correlations in pp collisions at 2.76 and 7 TeV in CMS

Sandra S. Padula

IFT – UNESP

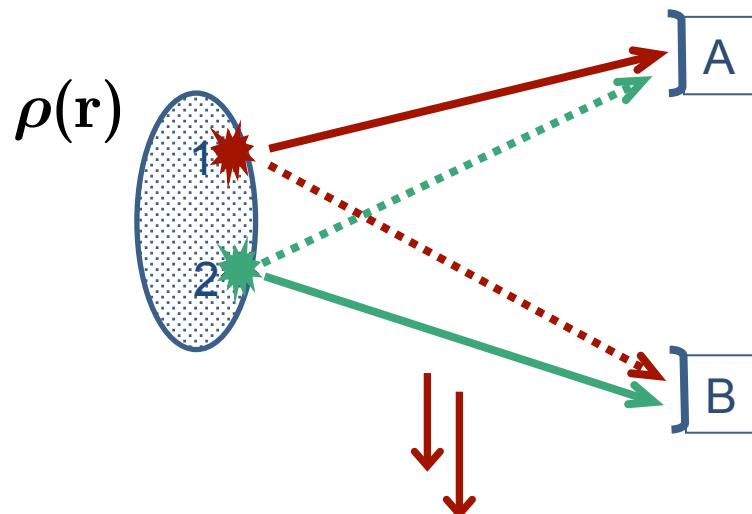

For the CMS Collaboration

WPCF 2014, Gyöngyös, Hungary, 25-28 September, 2014

Briefly revisiting the basic HBT concepts

- Detecting two identical bosons emitted from sources 1 & 2 at A & B

- Two-boson correlation function \rightarrow reflects source dimensions

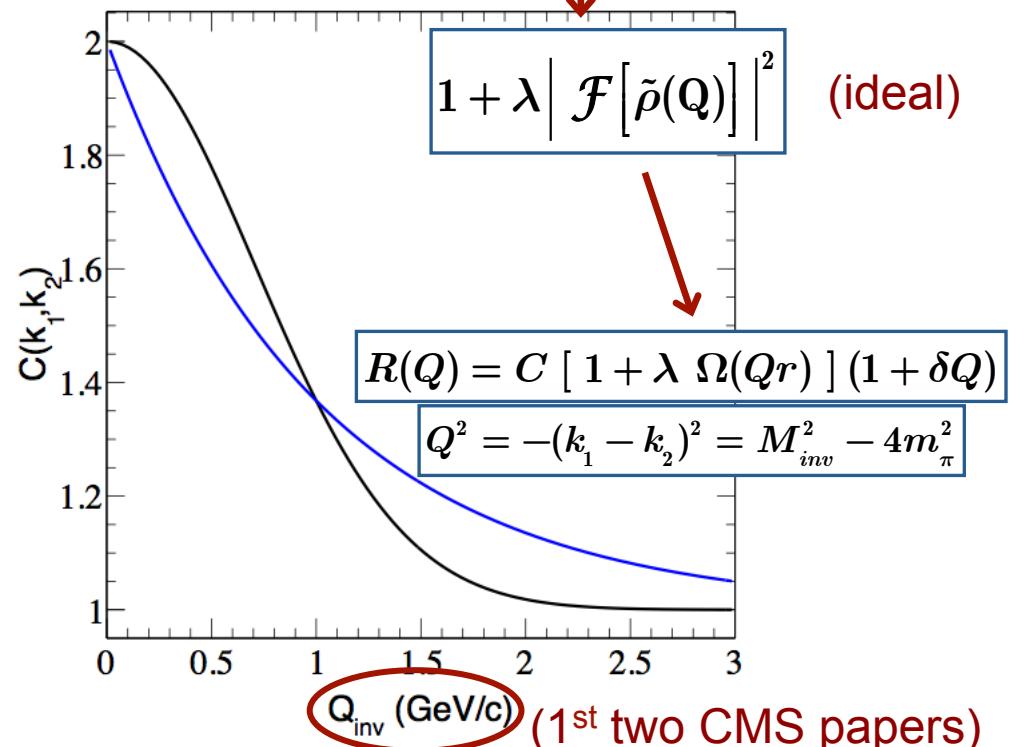

– Correlation Function:

$$R(Q = k_1 - k_2) = \frac{P_2(k_1, k_2)}{P_1(k_1)P_1(k_2)}$$

$$1 + \lambda |\mathcal{F}[\tilde{\rho}(Q)]|^2 \quad (\text{ideal})$$

$$R(Q) = C [1 + \lambda \Omega(Qr)] (1 + \delta Q)$$

$$Q^2 = -(k_1 - k_2)^2 = M_{inv}^2 - 4m_\pi^2$$

HBT in 1D @ CMS single & double ratios

- Experimentally

$$R^{\text{exp}}(Q = k_1 - k_2) = \frac{S(k_1, k_2)}{\mathcal{B}(k_1, k_2)}$$

Same event pairs
(with BEC)

Different Reference Samples
(no BEC)

First 2 CMS papers on HBT

- Background (reference sample) pair selection

- » Same event, \neq charges (☺ resonances)
- » Rotation of 1 track of the pair
- » Mixed events (☺)

Coulomb FSI
Gamow factor applied to data

- Double ratios → reduce bias:

$$\mathcal{R}(Q) = \frac{R(Q)}{R_{MC}(Q)} = \left[\frac{\frac{dN_{\text{signal}} / dQ}{dN_{\text{ref}} / dQ}}{\frac{dN_{MC, \text{like}} / dQ}{dN_{MC, \text{ref}} / dQ}} \right] \quad (\text{No BEC in MC})$$

$$\Upsilon_{ss}(\eta) = \frac{\eta / Q}{e^{\eta/Q} - 1}$$

$$\eta = 2\pi\alpha_{em} m_\pi$$

Data and MC samples – Track selection

\sqrt{s}	pp collisions	
	Data Sample	Monte Carlo
2.76 TeV	Minimum bias/2013 (3.4 M)	Pythia 6 Z – 2 tune (2 M)
7 TeV	MB Commissioning Run (23 M)	
7TeV	MB 2010 A (23 M)	Pythia 6 Z – 2 tune (23 M)
7 TeV	MB 2010 B (4 M)	

- Track selection cuts

- Tracks associated with most populated vertex
- $\chi^2 < 5$
- $d_{xy} < 0.15 \text{ cm}$
- $R_{\min} > 20 \text{ cm}$
- $p_T > 0.2 \text{ GeV}/c$
- $\eta < |2.4|$

This analysis:
charged hadrons (h^\pm)
(assumed to be dominated by π 's)

Extracting results: fit functions – 1D

- Symmetric Lévy stable distribution with index of stability a

$$\mathcal{R}(Q_{\text{inv}}) = C[1 + \lambda e^{-(Q_{\text{inv}} R_{\text{inv}})^a}] (1 + \delta Q_{\text{inv}})$$

□ relative and average momenta of the pair

$$Q_{\text{inv}}^2 = -(k_1^\mu - k_2^\mu) \cdot (k_{1_\mu} - k_{2_\mu}) = m_{\text{inv}}^2 - 4m_{\pi^2}$$

$$k_\mu = \frac{k_{1_\mu} + k_{2_\mu}}{2}$$

□ Limit $a=1 \rightarrow$ exponential function

Fourier transform of Cauchy-Lorentz source

$$\mathcal{R}(q) = C[1 + \lambda e^{-QR}] (1 + \delta Q) \quad S(r) = \frac{1}{2\pi^2} \frac{R}{r^2 + (\frac{1}{2}R)^2}$$

□ Limit $a=2 \rightarrow$ Gaussian distribution

Fourier transform of Gaussian source

$$\mathcal{R}(q) = C[1 + \lambda e^{-Q^2 R^2}] (1 + \delta Q) \quad \frac{1}{(\sqrt{2\pi}R)^3} e^{r^2/(2R^2)}$$

Fit functions summary: 1D – 2 D – 3D

- Lévy distribution with index of stability a
 - $a = 1 \rightarrow \text{exponential}$; $a=2 \rightarrow \text{Gaussian}$

□ 1D

$$\mathcal{R}(Q_{\text{inv}}) = C[1 + \lambda e^{-(Q_{\text{inv}} R_{\text{inv}})^a}] (1 + \delta Q_{\text{inv}})$$

□ 2-D

$$\begin{aligned} \mathcal{R}(q_T, q_L) &= C \left\{ 1 + \lambda \exp \left[- \left| q_T^2 R_T^2 + q_L^2 R_L^2 + 2q_T q_L R_{LT}^2 \right|^{\frac{a}{2}} \right] \right\} \\ &\times (1 + \alpha q_T + \beta q_L) \end{aligned}$$

$a = 1$ Stretched Exponentials

□ 3 D

$$\begin{aligned} \mathcal{R}(q_S, q_L, q_O) &= C \left\{ 1 + \lambda \exp \left[- \left| q_S^2 R_S^2 + q_L^2 R_L^2 + q_O^2 R_O^2 + 2q_O q_L R_{LO}^2 \right|^{\frac{a}{2}} \right] \right\} \\ &\quad (1 + \alpha q_S + \beta q_L + \gamma q_O) \end{aligned}$$

T. Csörgő, Hegyi, W. A. Zajc, Eur. Phys. J. **C36** (2004) 67

- (in the **LCMS** → $k_L = (k_{1L} + k_{2L})/2 = 0$ and cross-term disappears for sources symmetric in longitudinal direction)

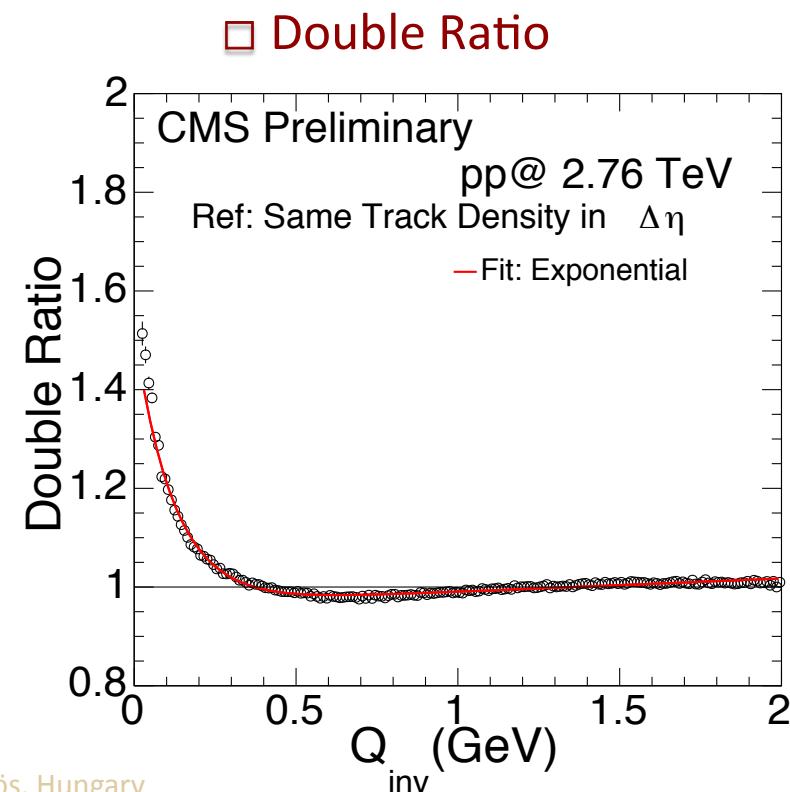

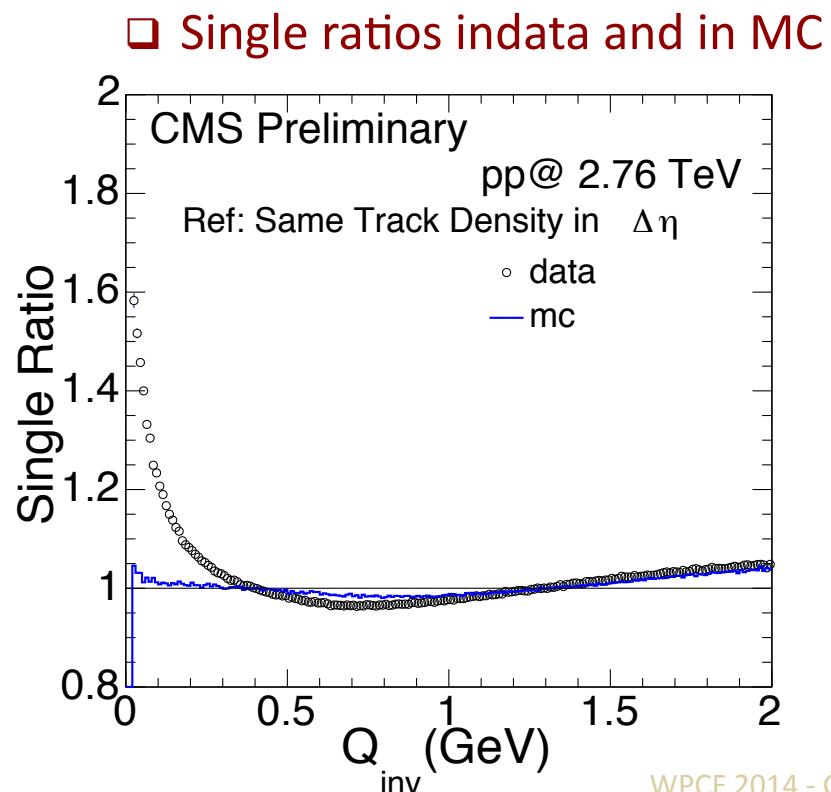

Summary of results in 1-dimension

1-D Single and Double Ratios in pp @ 2.76 TeV

$$R^{\text{exp}}(Q = k_1 - k_2) = \frac{S(k_1, k_2)}{\mathcal{B}(k_1, k_2)}$$

Reference sample (mixed events: similar N_{ch} within same η range)

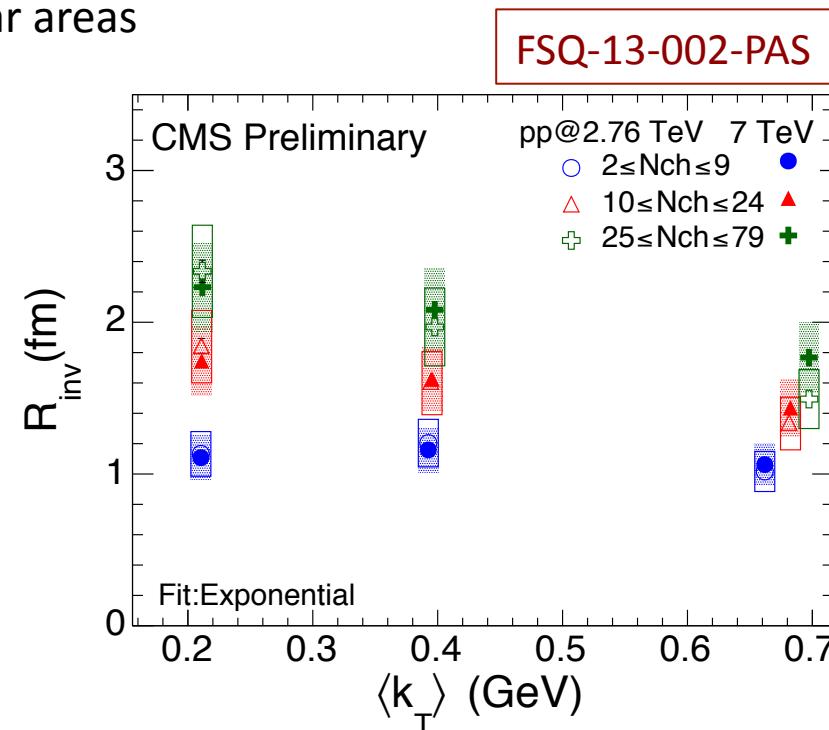

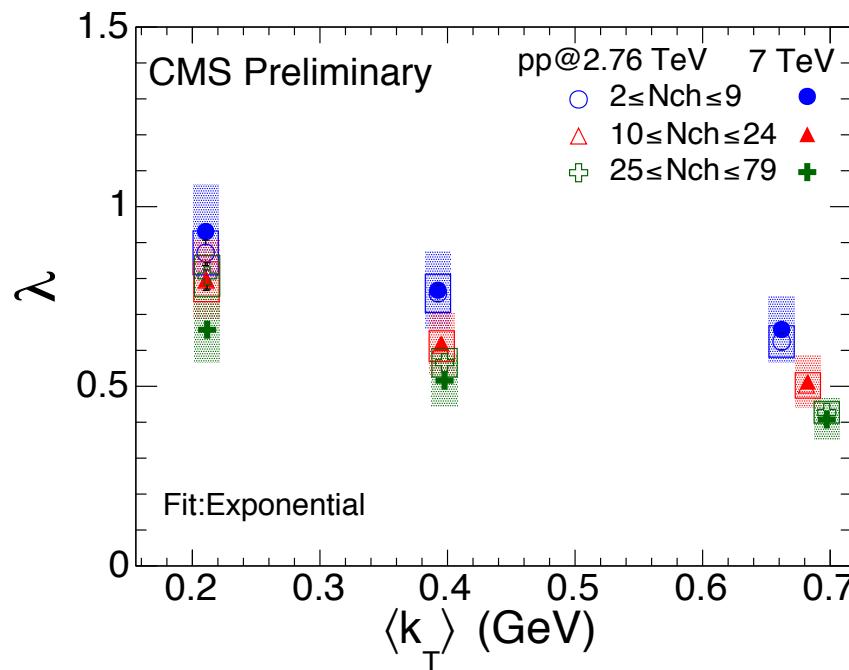

Signal distribution

Double ratios and fit parameters R_{inv} and λ

– 1D Double ratios investigated

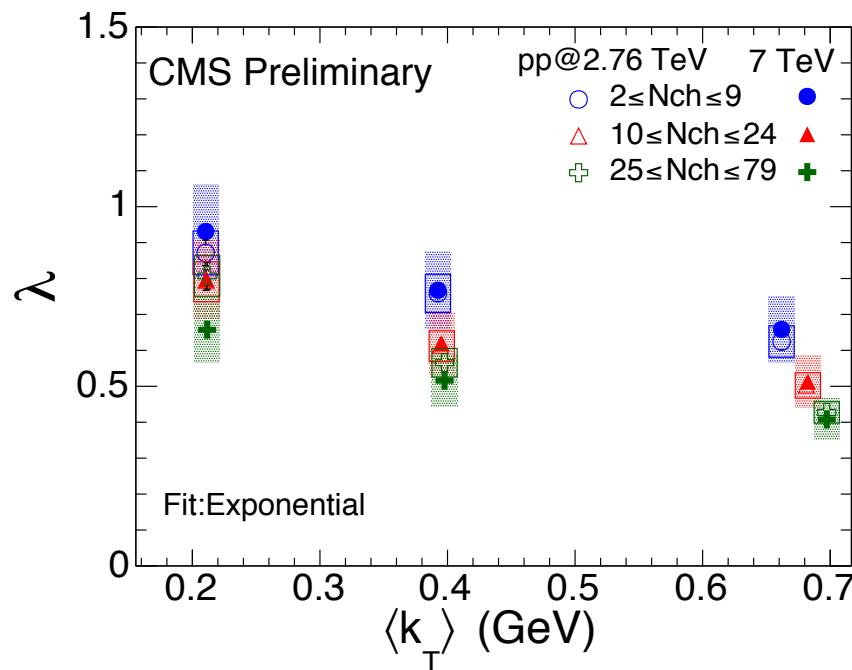

- ❑ pp collisions at 2.76 and 7 TeV
- ❑ differentially in N_{ch} and k_T bins
- ❑ Fit function: exponential
- ❑ Uncertainties in plots below
 - statistical → error bars
 - systematic → shaded rectangular areas

Double ratios and fit parameters R_{inv} and λ

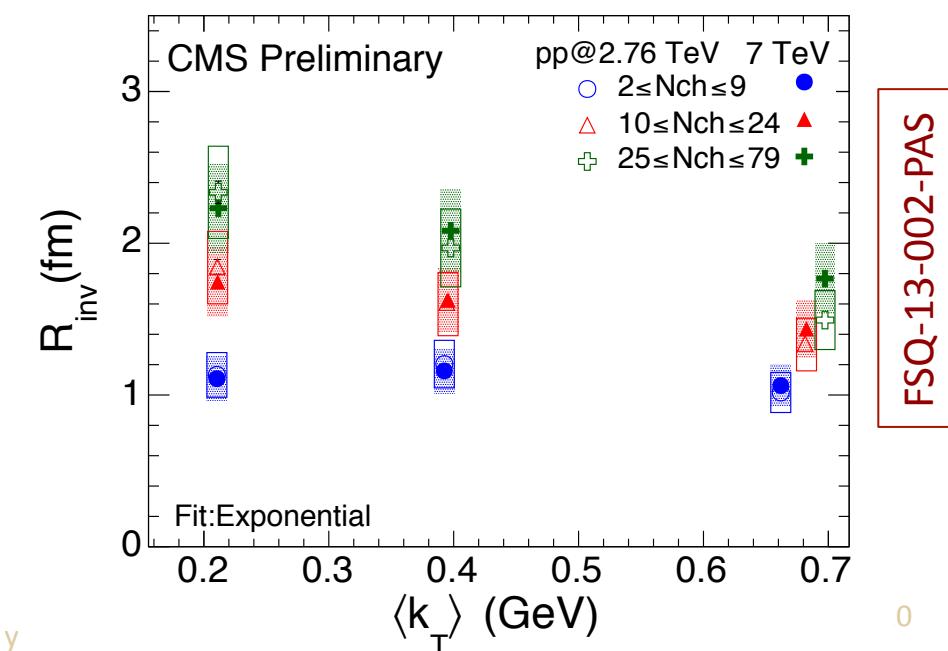

– 1D Double ratios investigated

- pp collisions at 2.76 and 7 TeV
- differentially in N_{ch} and k_T bins
- Fit function: exponential
- Uncertainties in plots below
 - statistical → error bars
 - systematic → shaded rectangular areas

– Summary of results:

- Radius fit parameter – R_{inv}
 - increase with N_{ch}
 - decrease with k_T
- Intercept parameter – λ
 - decreases with N_{ch} (3 bins only)
 - decreases with k_T

Radius fit (exponential) parameter vs. $\langle N_{ch} \rangle$

- Curves: $R_{inv} = a N_{ch}^{1/3}$ – comparing results at 0.9 TeV, 7 TeV and 2.76 TeV
 - K_T integrated results (error bars: statistical and systematic)
 - $R_{inv} \leftrightarrow$ increase particle production with increasing collision energy (\approx scaling w/ \sqrt{s})

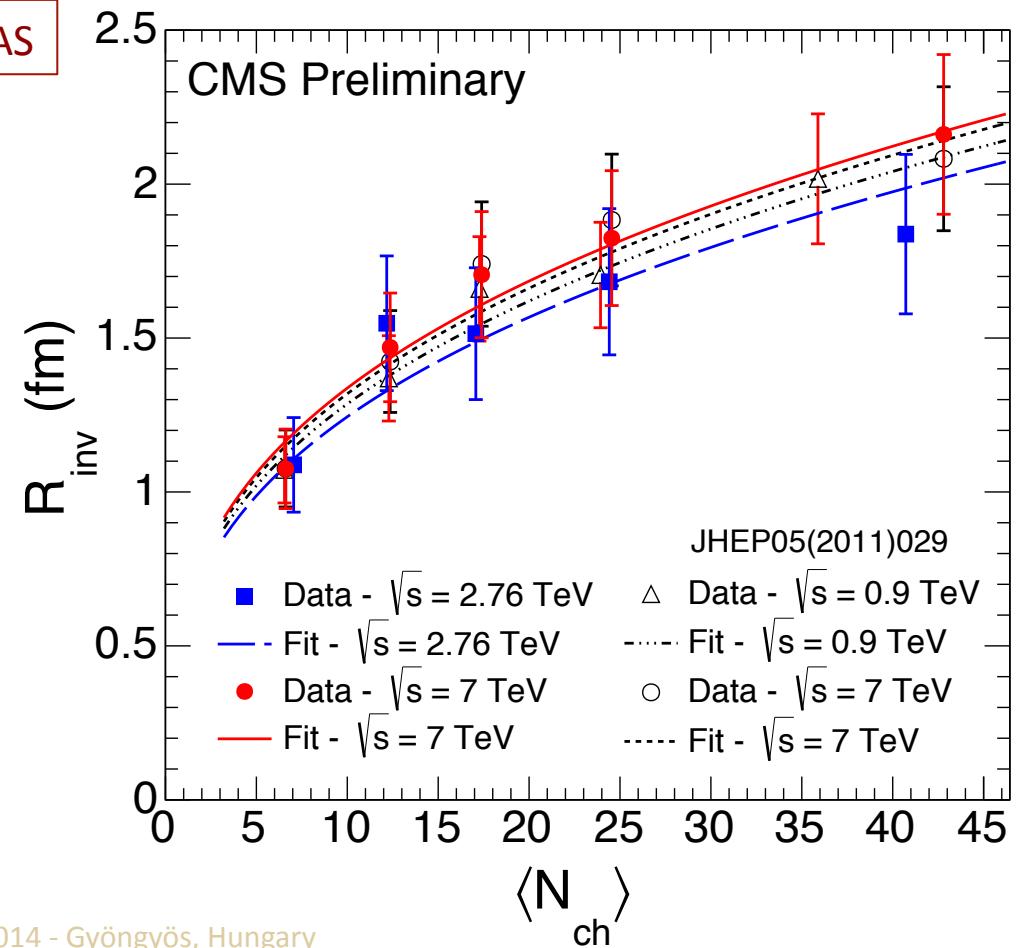

FSQ-13-002-PAS

- The proportionality parameter

a in of R as a function of $N_{ch}^{1/3}$

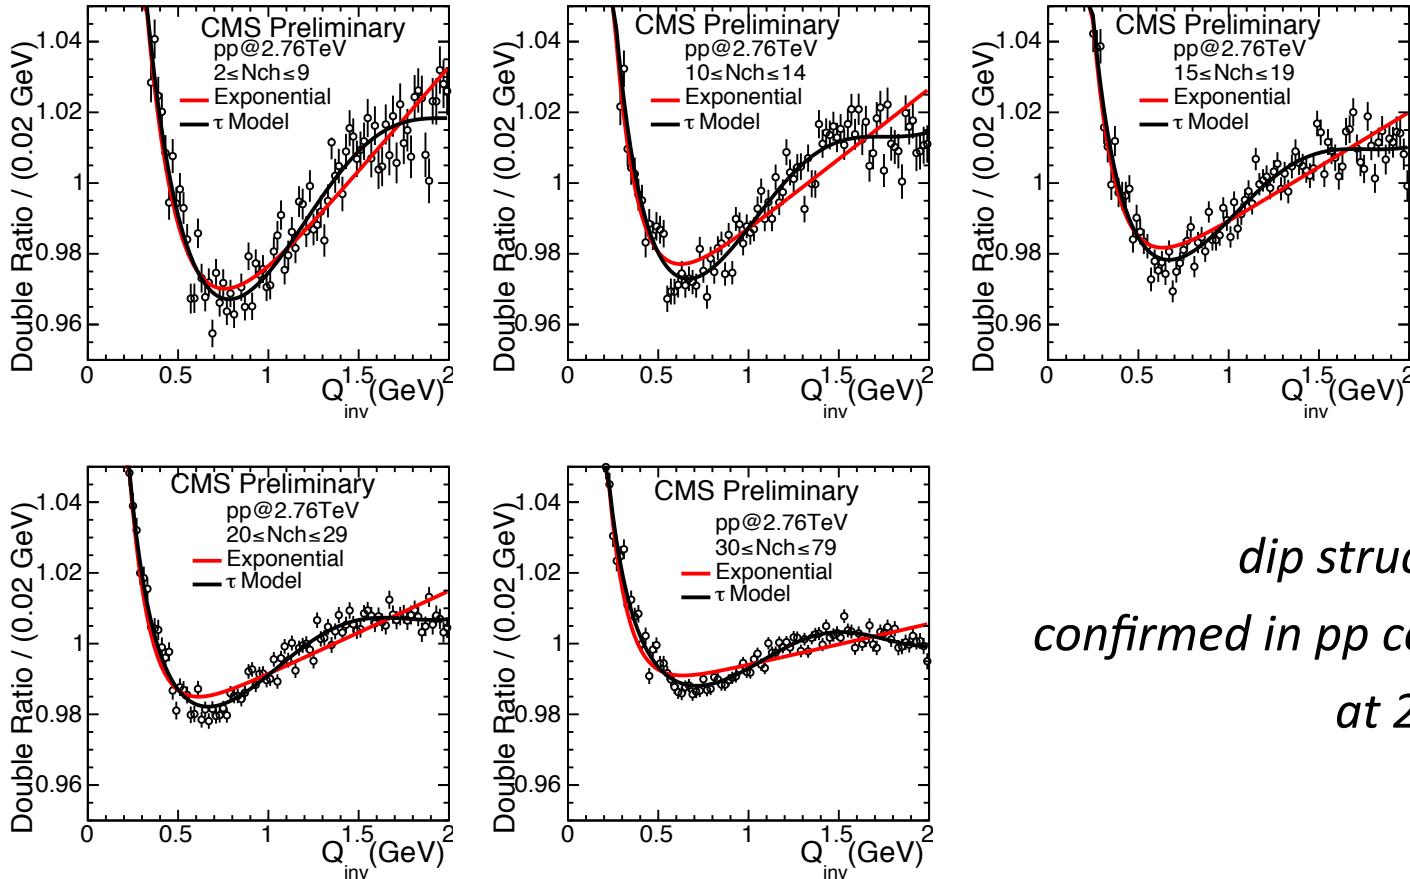

- at 0.9 TeV
 $a = [0.597 \pm 0.009]$ (fm)
- at 7 TeV
 $a = [0.612 \pm 0.007]$ (fm)
- at 2.76 TeV
 $a = [0.578 \pm 0.005]$ (fm)
- at 7 TeV (new results)
 $a = 0.621 \pm 0.001$

(in a : statistical uncert. only)

Double Ratios (Q_{inv}): study of the anticorrelation

FSQ-13-002-PAS

*dip structure →
confirmed in pp collisions
at 2.76 TeV*

- exponential fit (with long-range term) → **red**; τ -model → **black**
- Csörgő & Zimányi, N.P. A 517, 588 (1990); Metzger et al., P. L. B663, 114 (2008)]

$$R^*(Q) = C \left[1 + \lambda \left(\cos \left[(r_0 Q)^2 + \tan(\alpha \pi / 4) (Q r_\alpha)^\alpha \right] e^{-(Q r_\alpha)^\alpha} \right) \right] \cdot (1 + \delta Q)$$

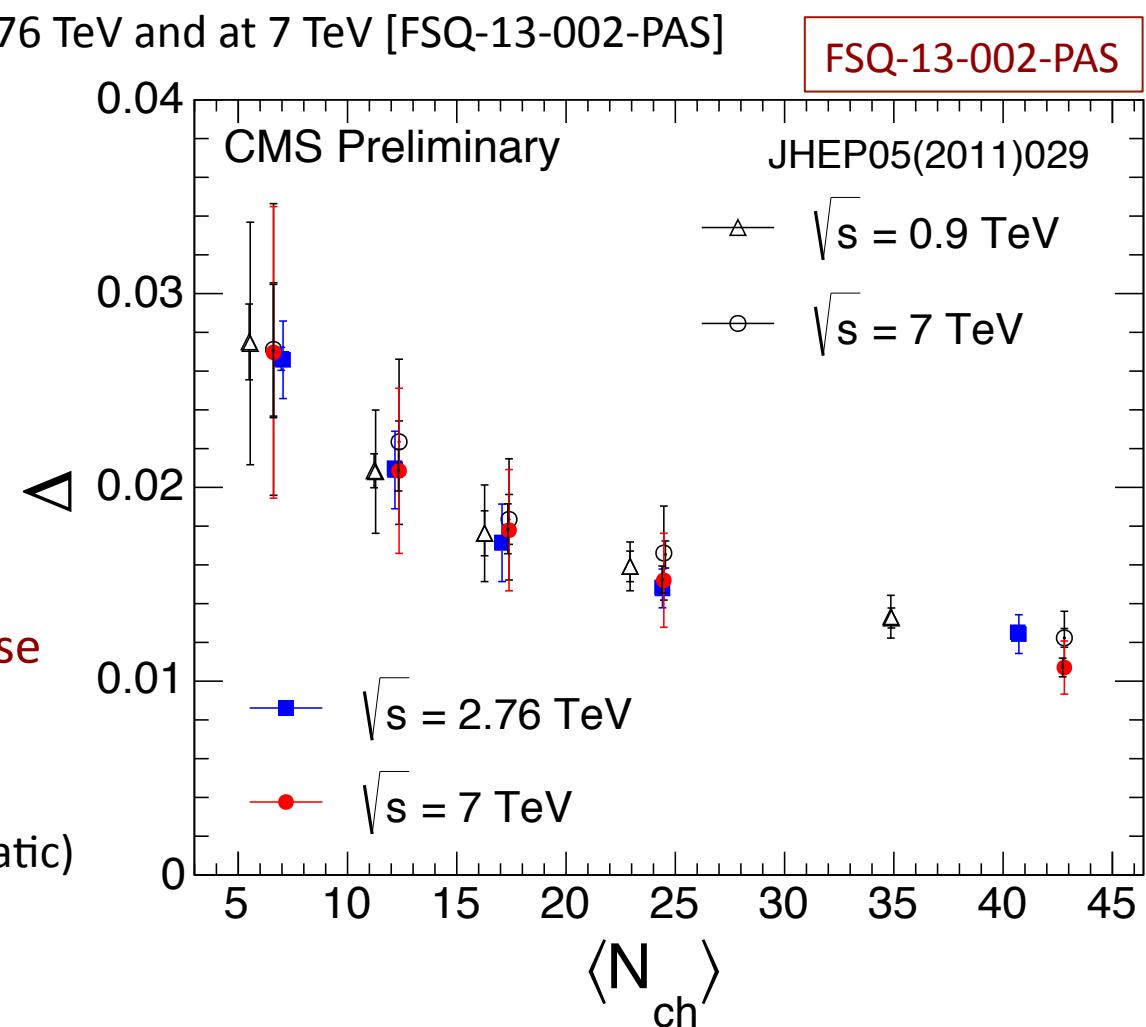

Quantifying the dip's depth

- Dip's depth (integrate in k_T)

- published results (0.9 & 7 TeV) [JHEP 05(2011)029]
+ new results at 2.76 TeV and at 7 TeV [FSQ-13-002-PAS]

- Summary:

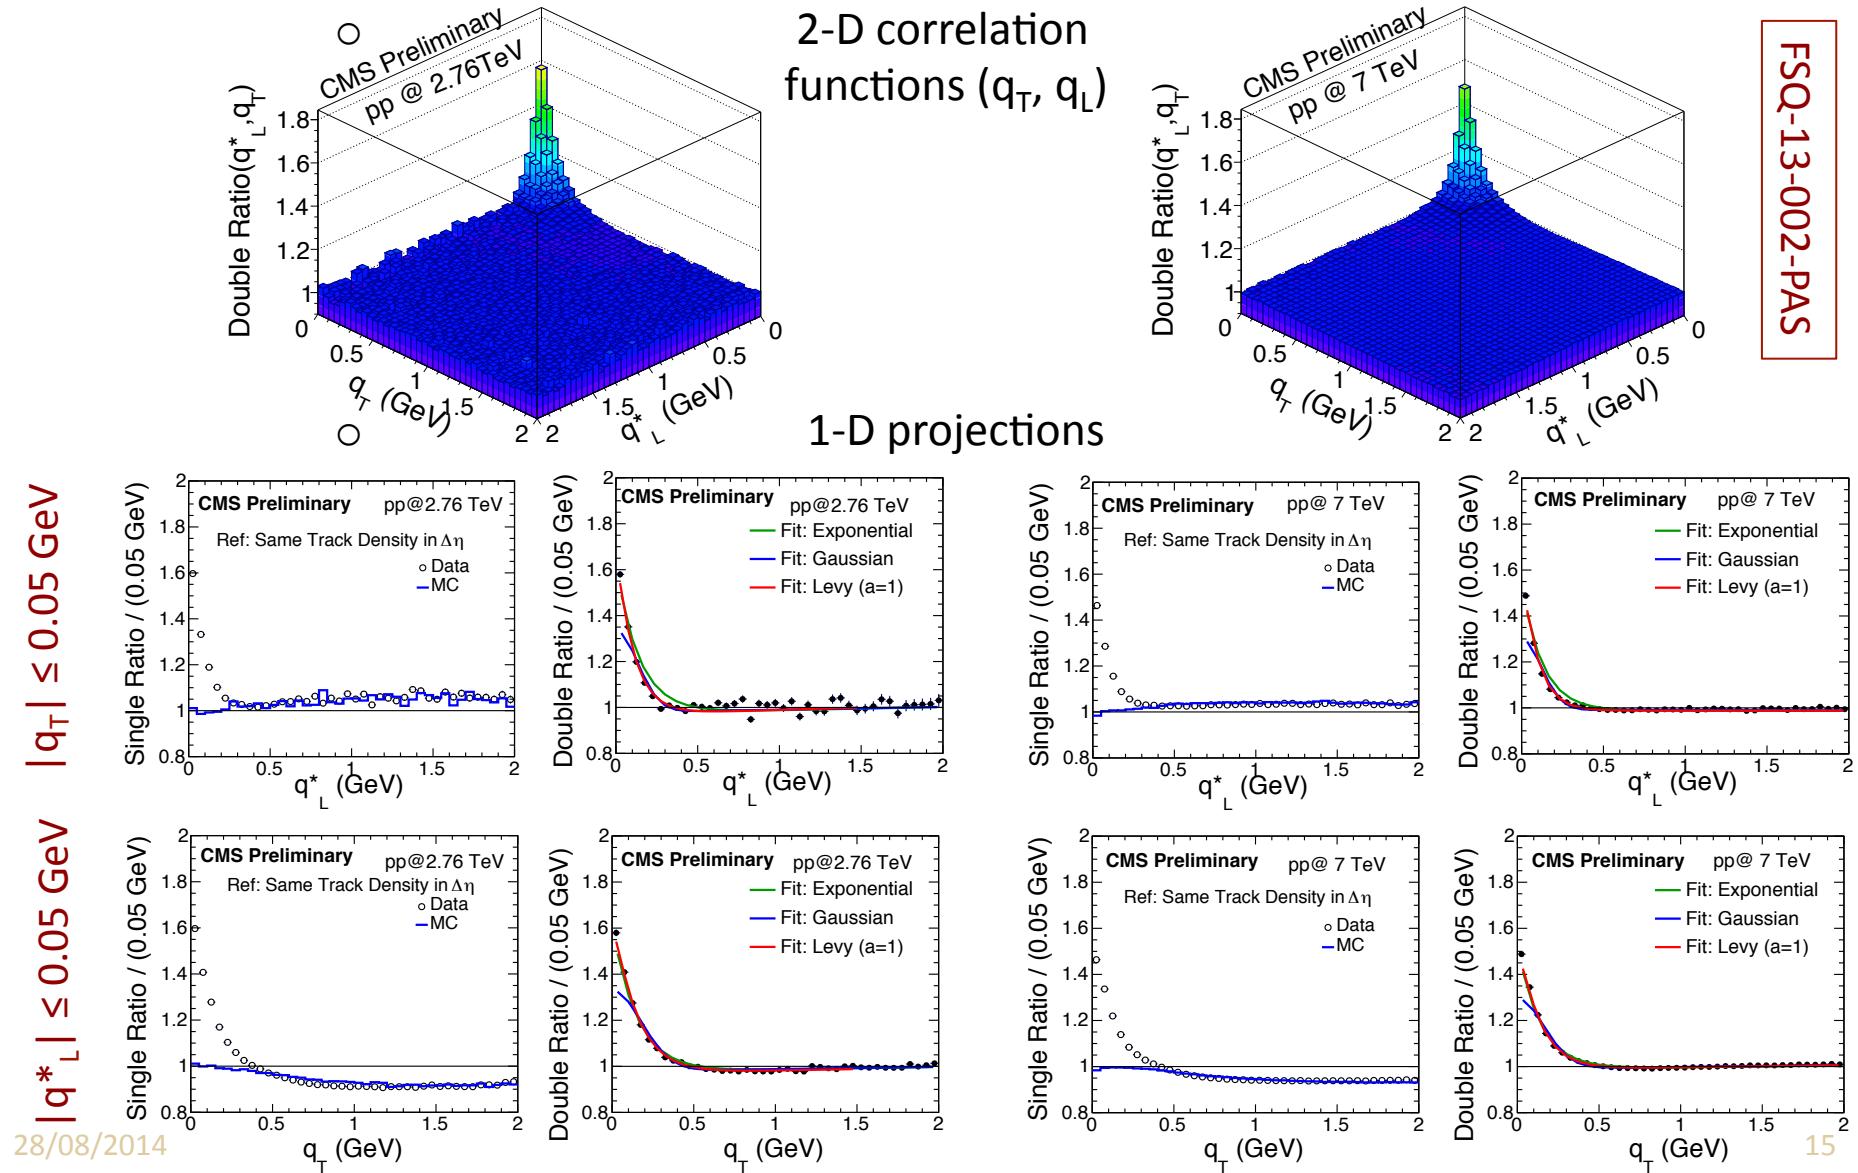

- previous and new results → consistent
 - \approx scaling with \sqrt{s}
 - dip's depth → decrease with N_{ch}
(error bars → systematic)

Summary of results in 2-dimensions

2-D DR(q_T, q_L): k_T and N_{ch} integrated

FSQ-13-002-PAS

2D results with *stretched exponential* fit function

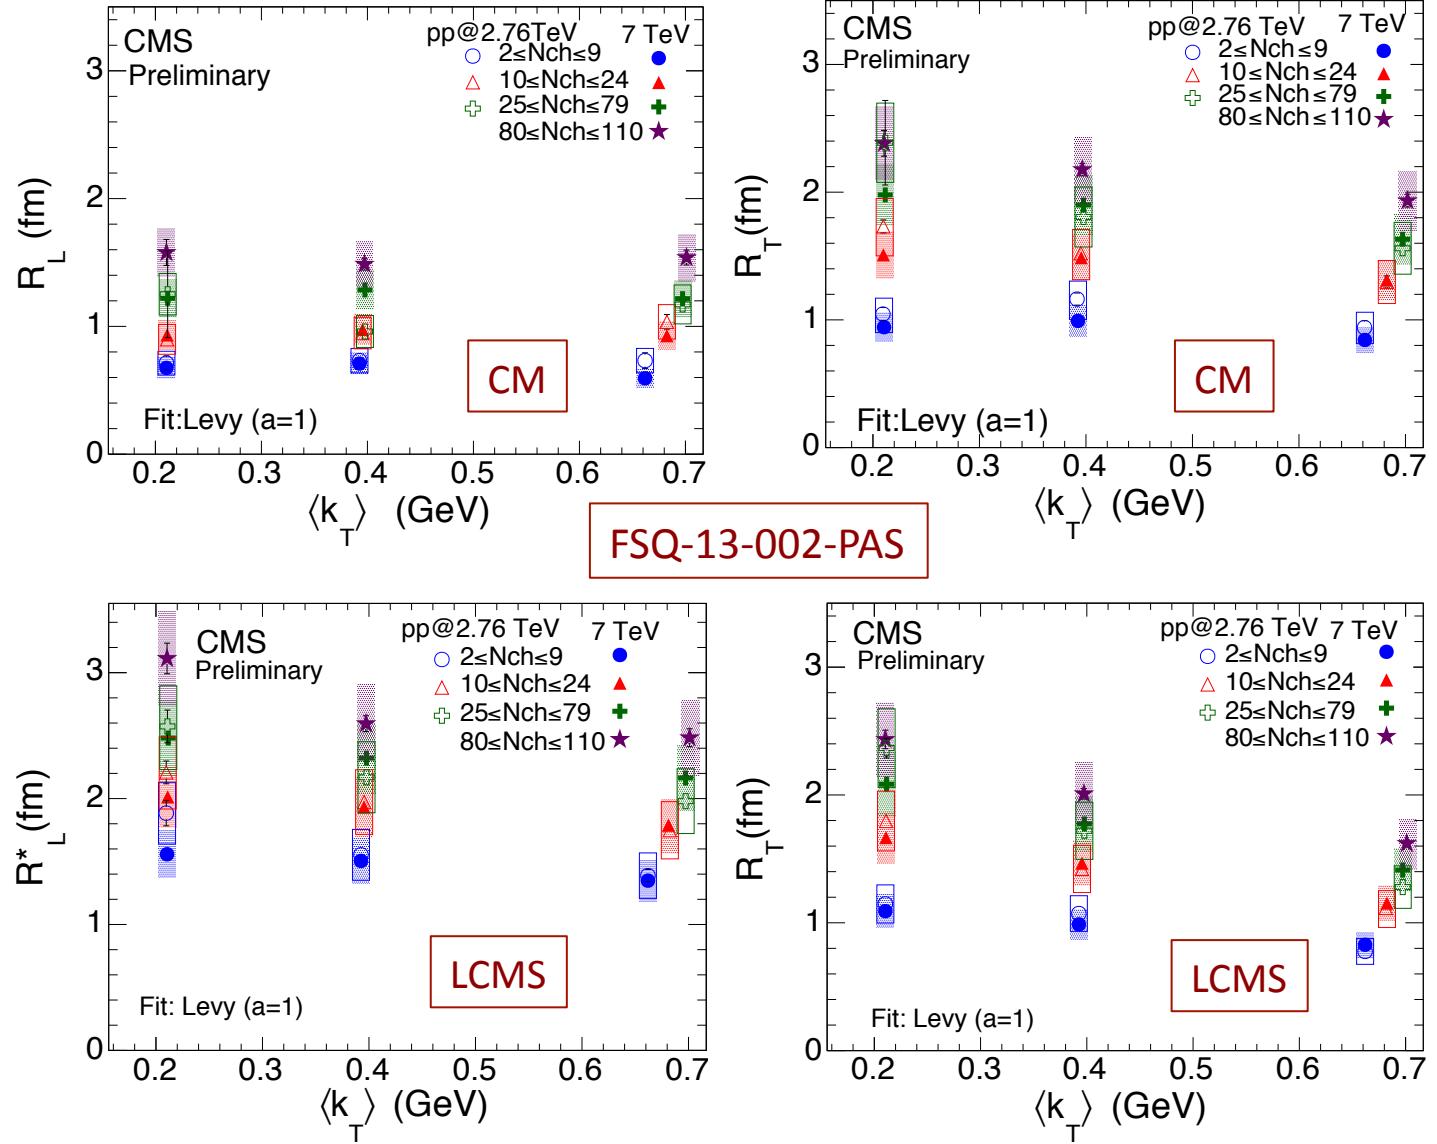

- For $R^{(*)}_L$ & R_T :

- CM frame

-  as N_{ch} 
-  as k_T 
(for large N_{ch})
- $R_L < R_T$

- LCMS

-  as N_{ch} 
-  as k_T 
(for larger N_{ch})
- Integrated
in k_T , N_{ch} :
- $R^*_L > R_L$
- $R^*_L > R_T$
(LCMS)

2D results with *stretched exponential* fit function

- For the intercept $\lambda^{(*)}$

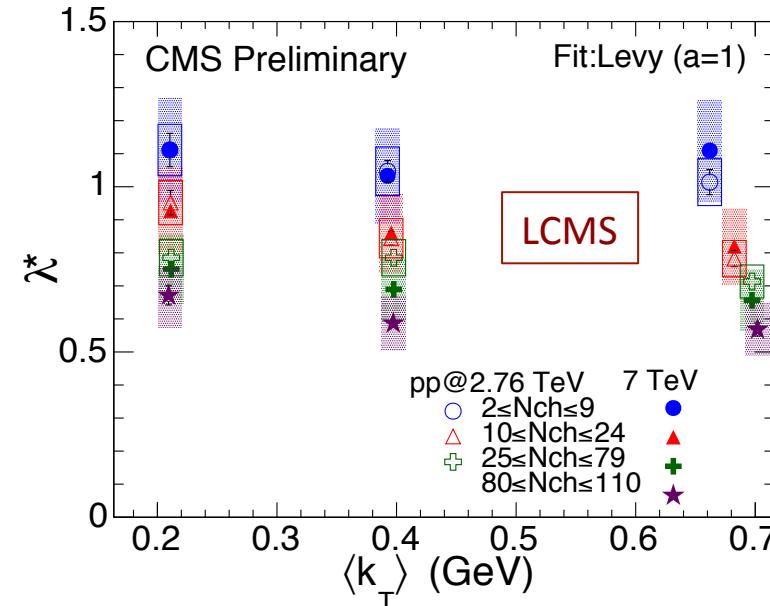

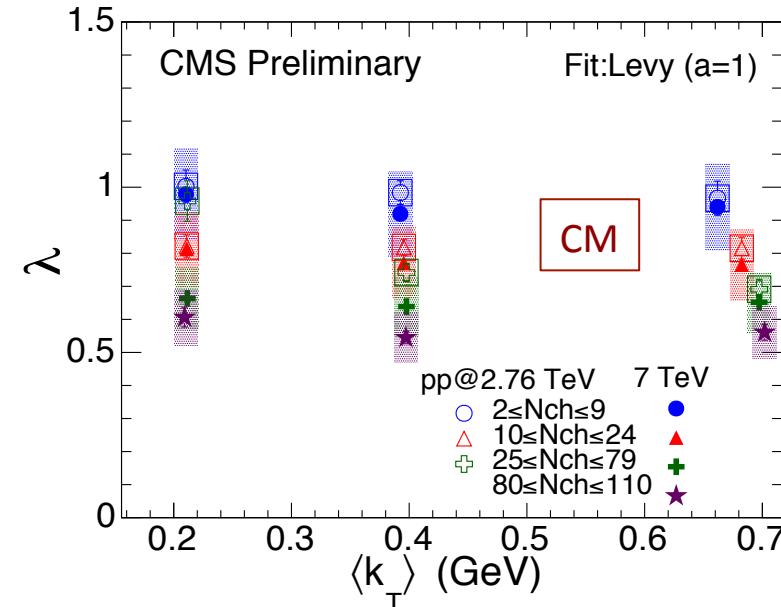

- CM frame

- ↘ as N_{ch} ↗
- almost flat as k_T ↗

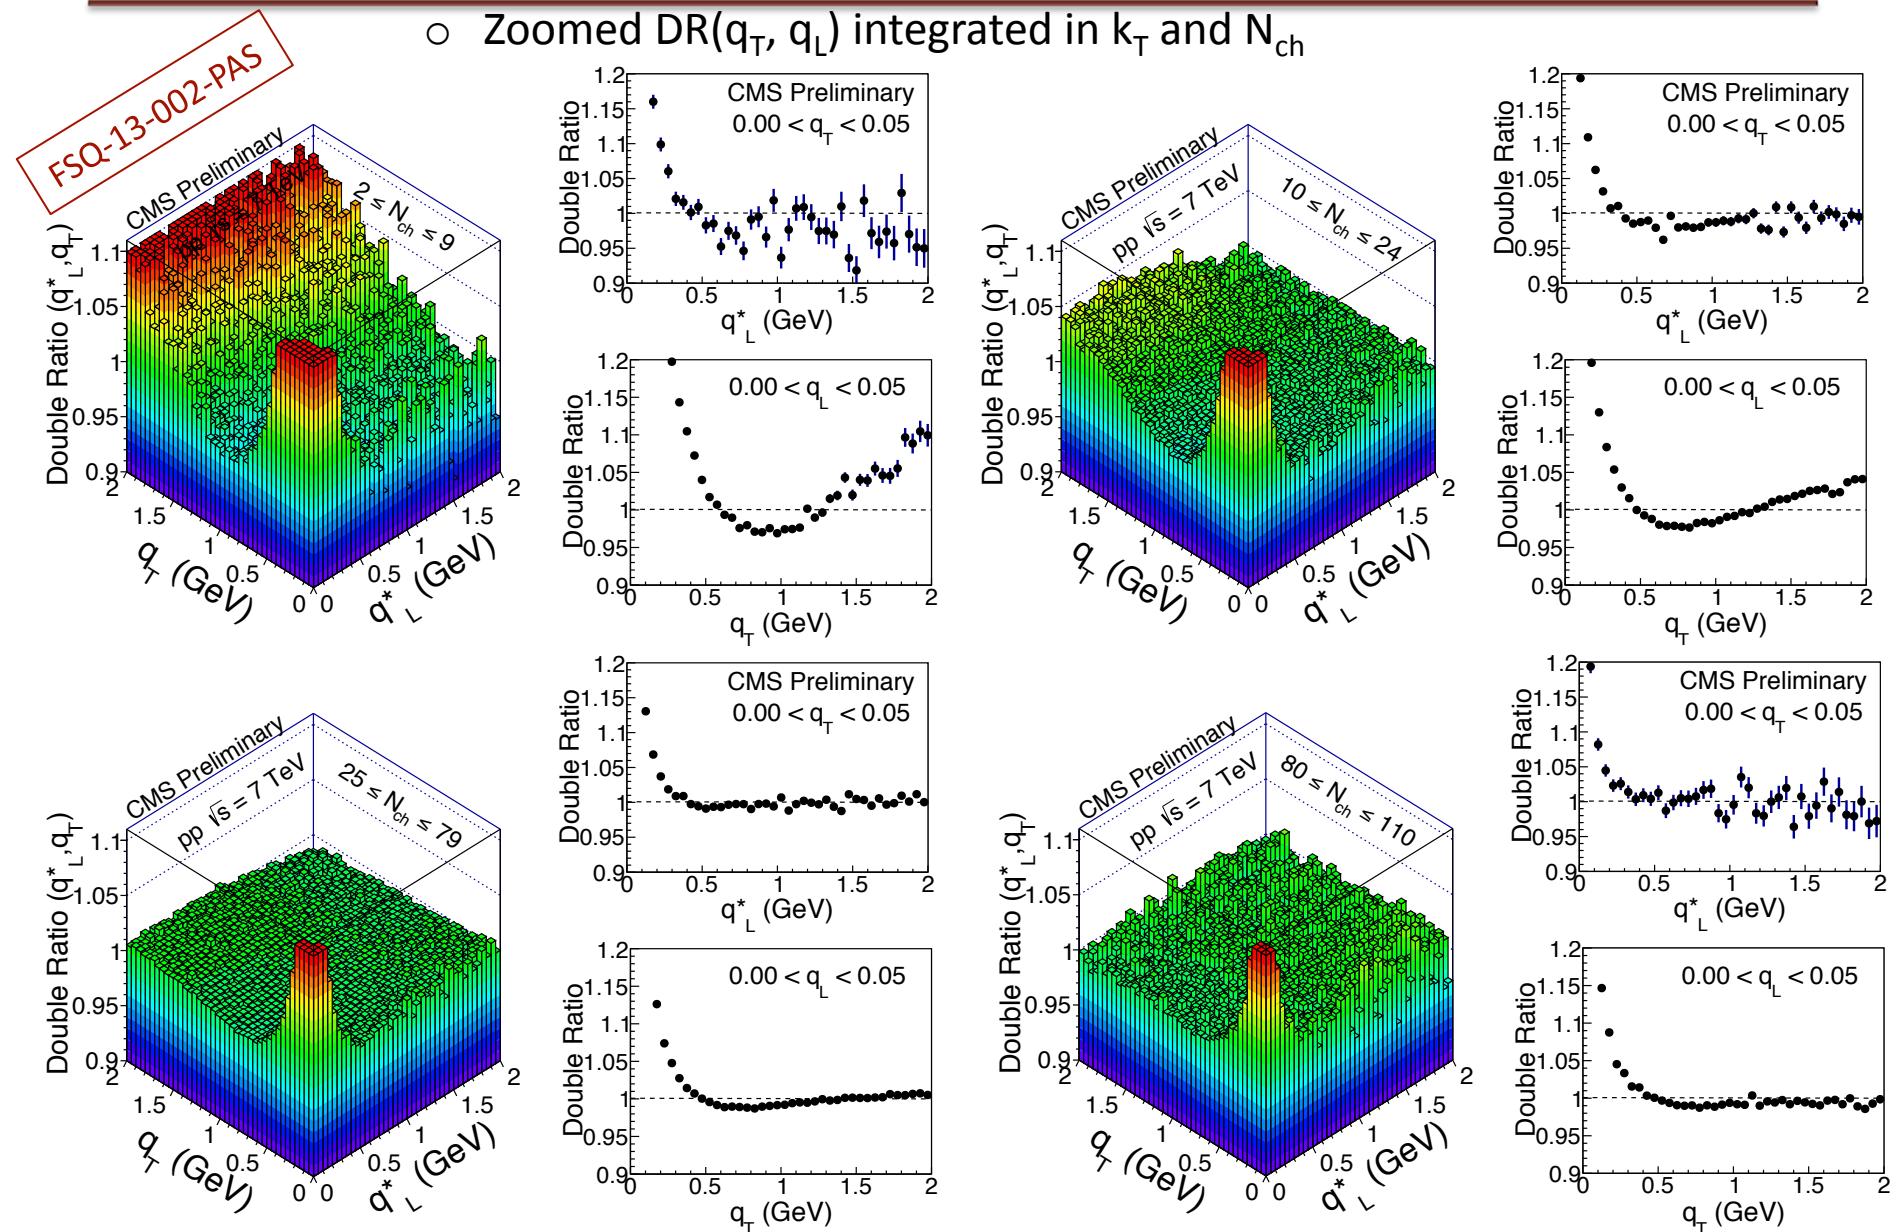

FSQ-13-002-PAS

- LCMS

- ↘ as N_{ch} ↗
- slight decrease as k_T ↗
(for larger N_{ch})

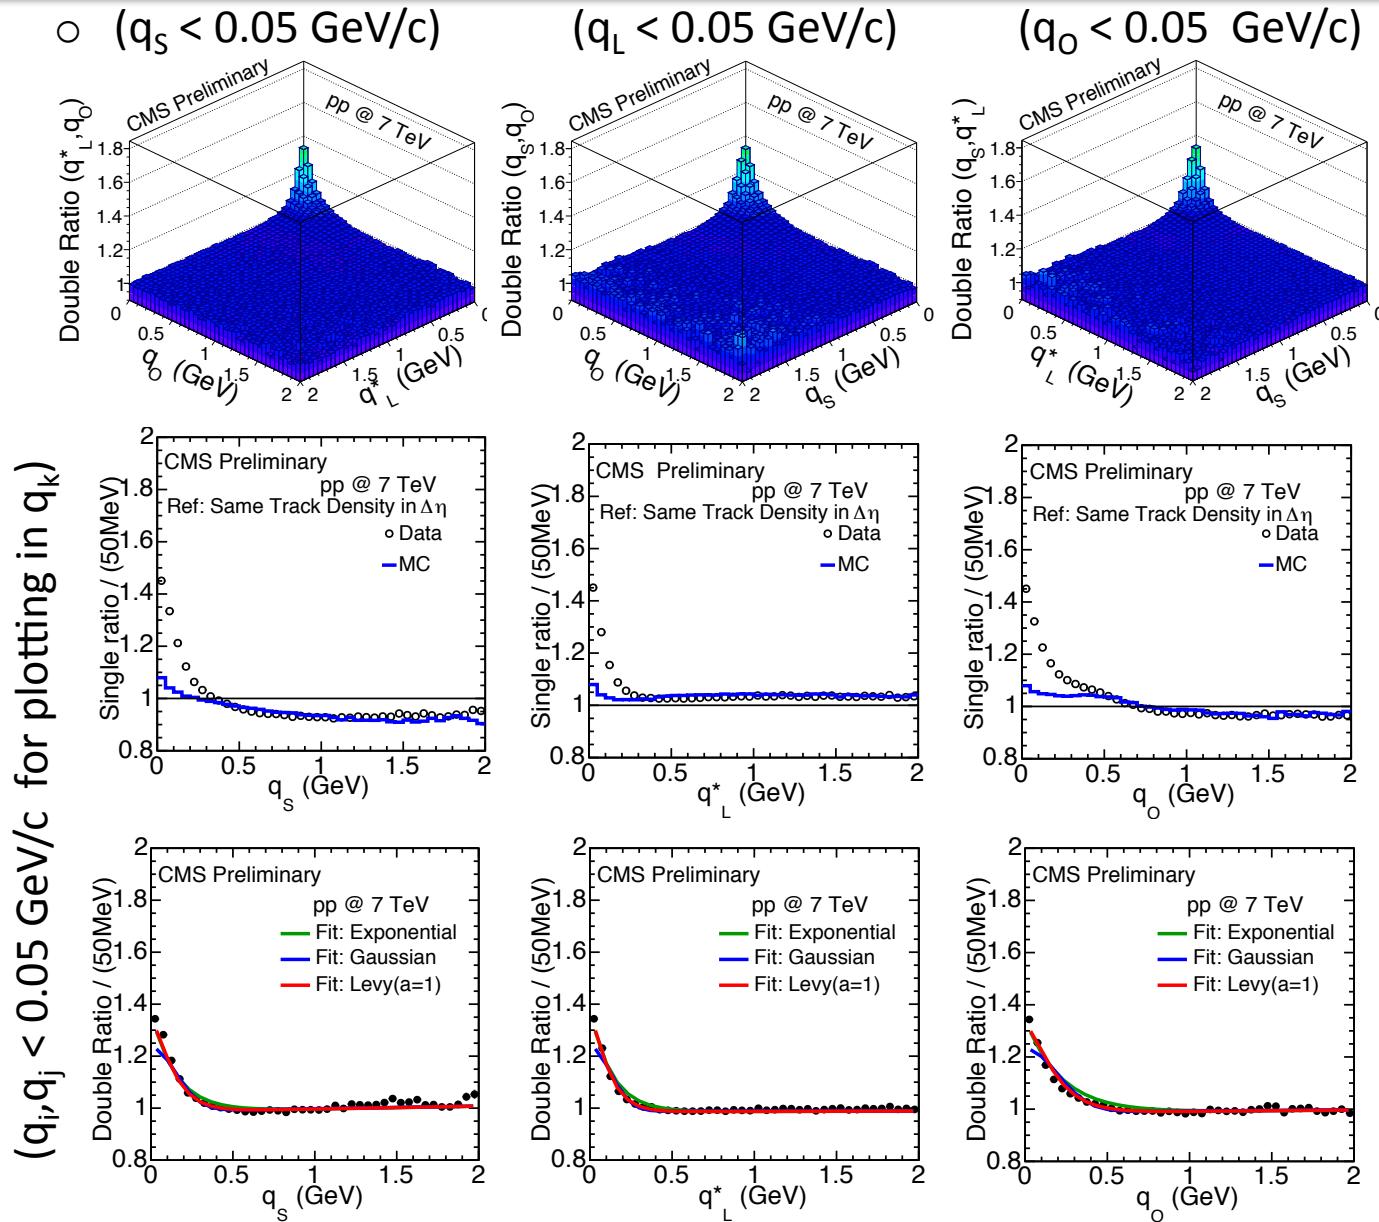

The anticorrelation in 2-D DR (q_T, q_L) - LCMS

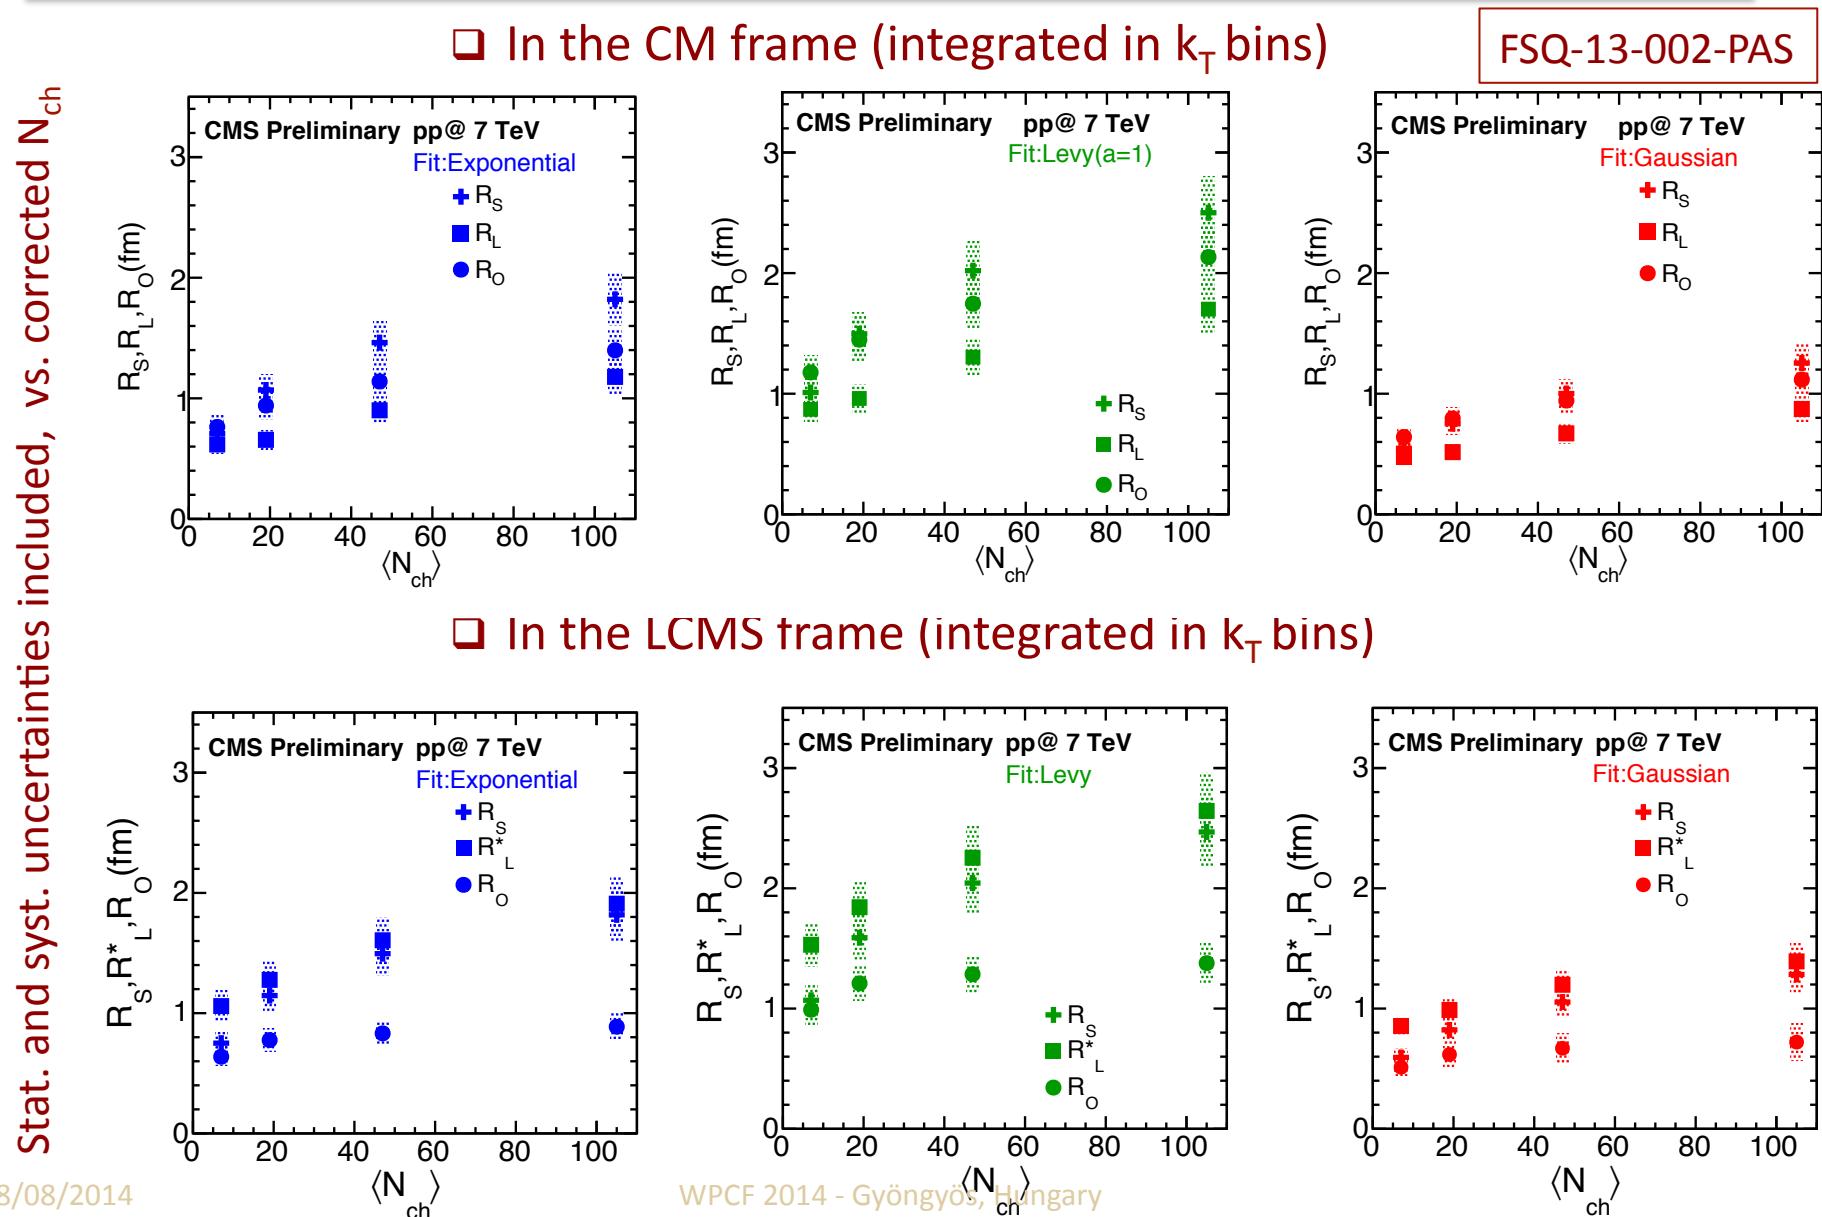

Summary of results in 3-dimensions

3-D Double Ratios (q_O , q_S , q_L) – in LCMS at 7 TeV

FSQ-13-002-PAS

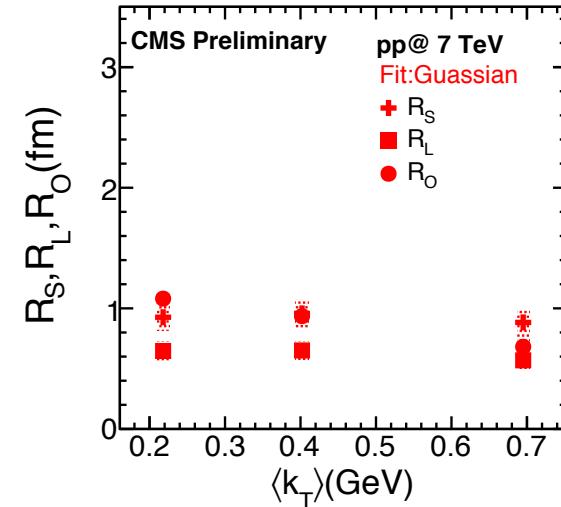

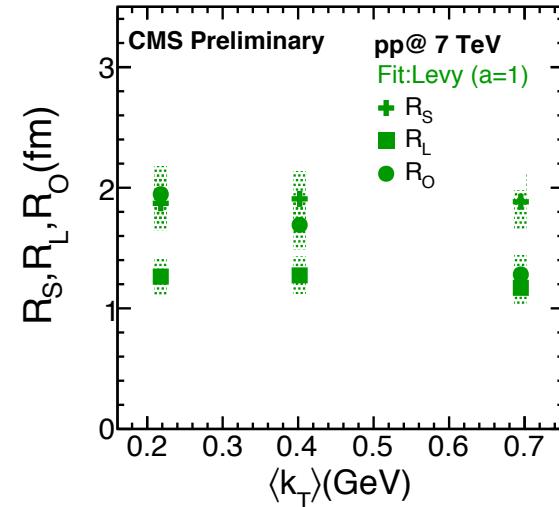

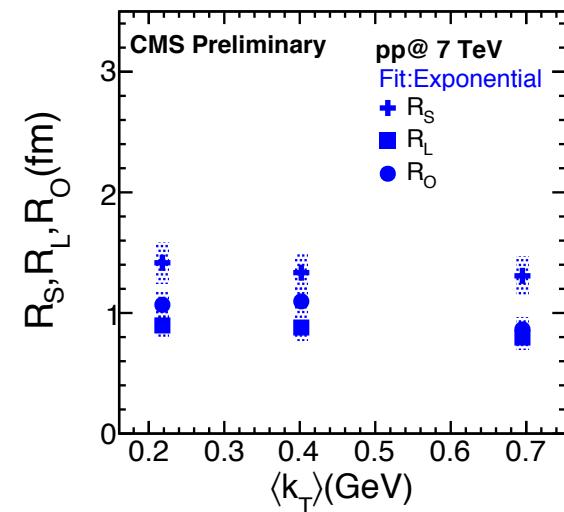

Results: R_S , R_L , R_O from different fit functions

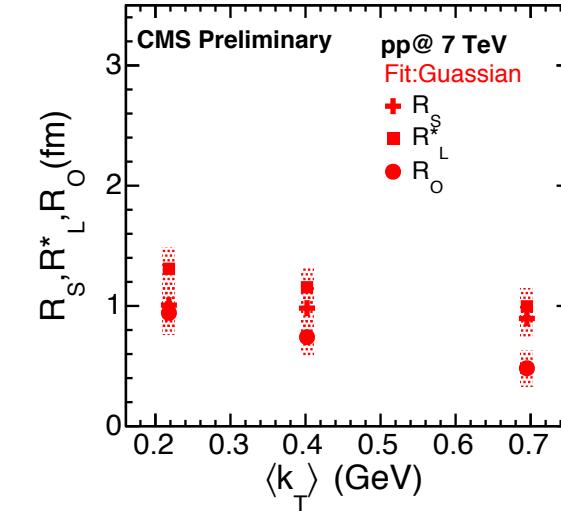

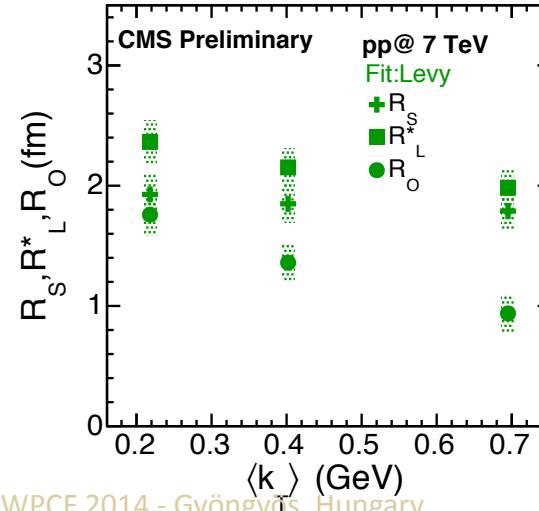

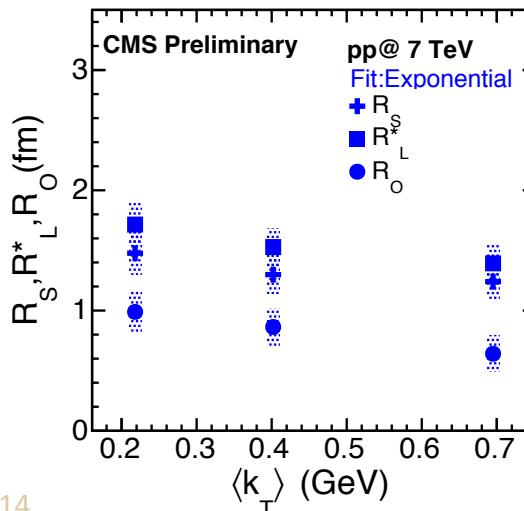

Results: R_S , R_L , R_O from different fit functions

Stat. and syst. uncertainties included, vs. corrected N_{ch}

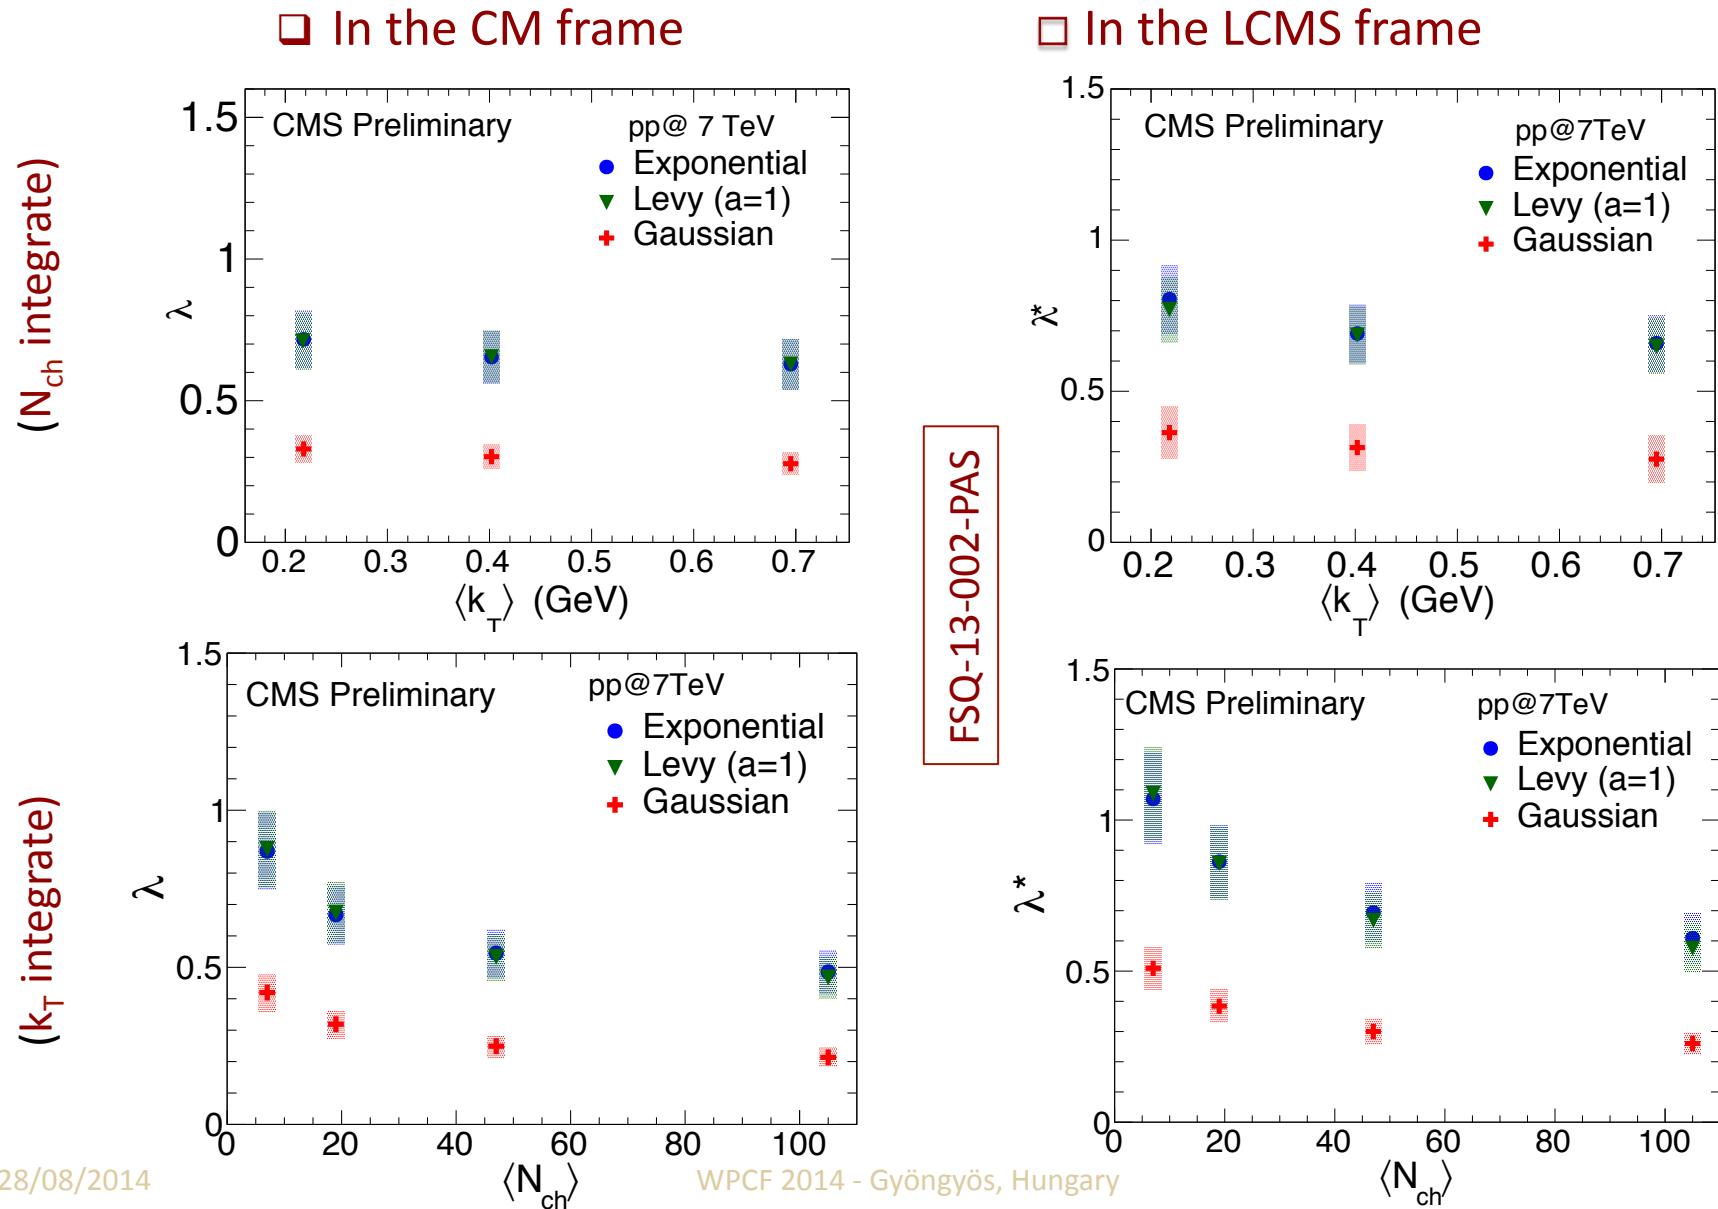

□ In the CM frame (integrated in N_{ch} bins)

□ In the LCMS frame (integrated in N_{ch} bins)

Results: λ , λ^* from different fit functions

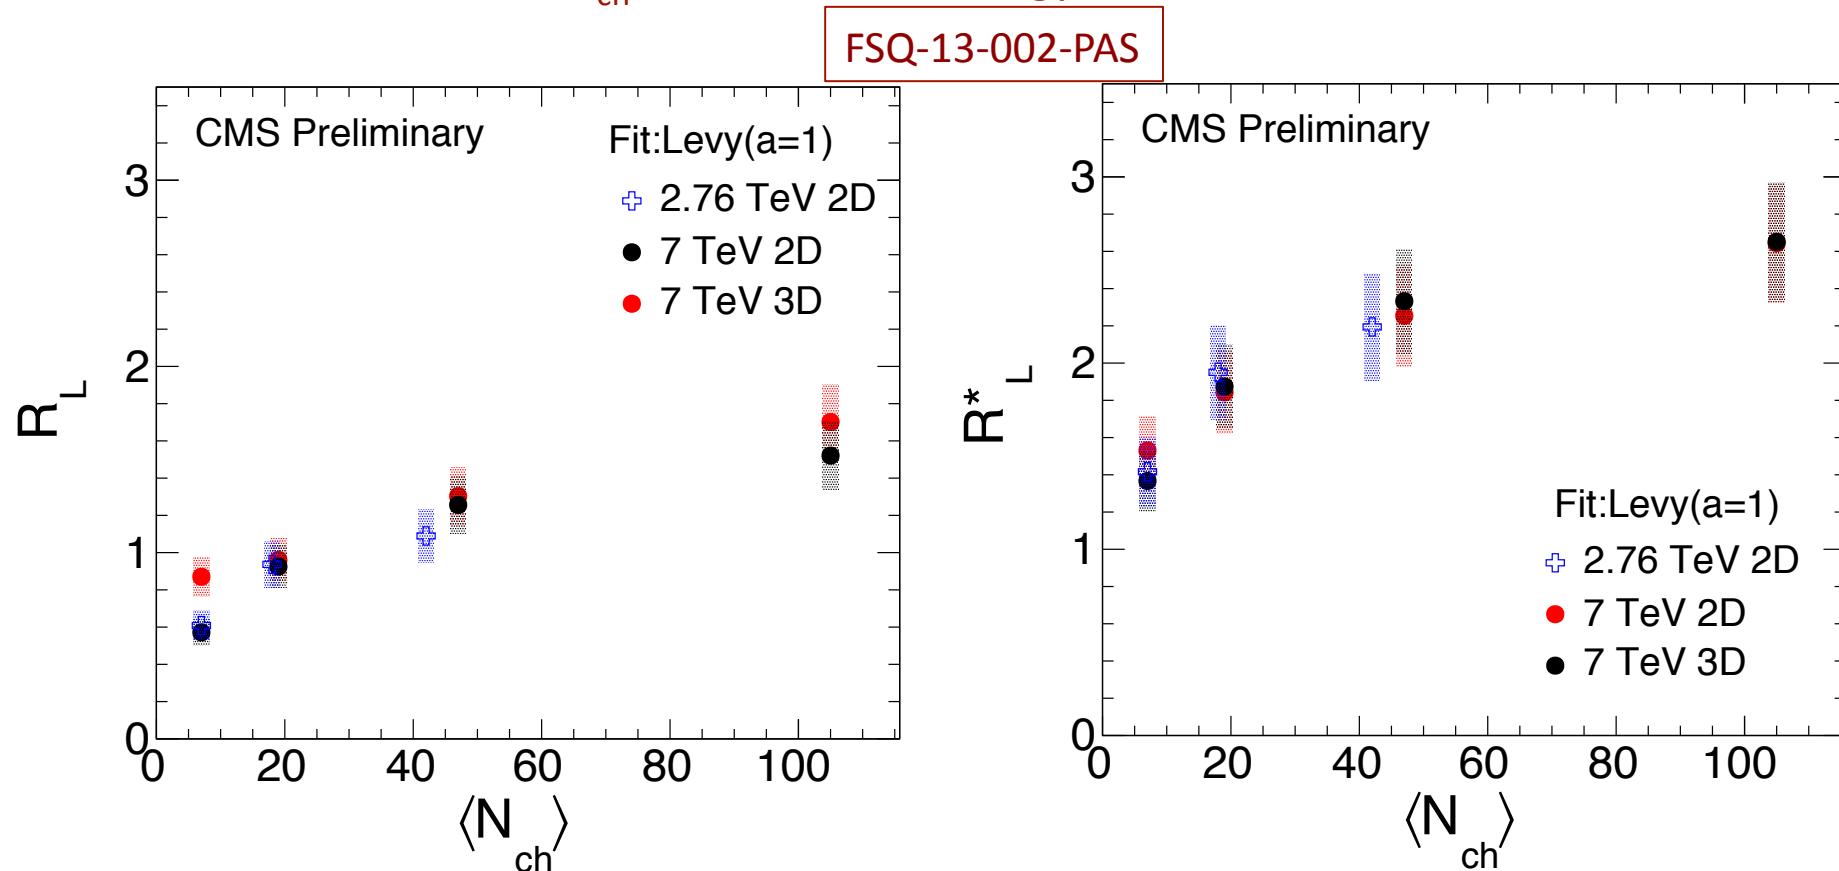

Compilation of the 3-D results

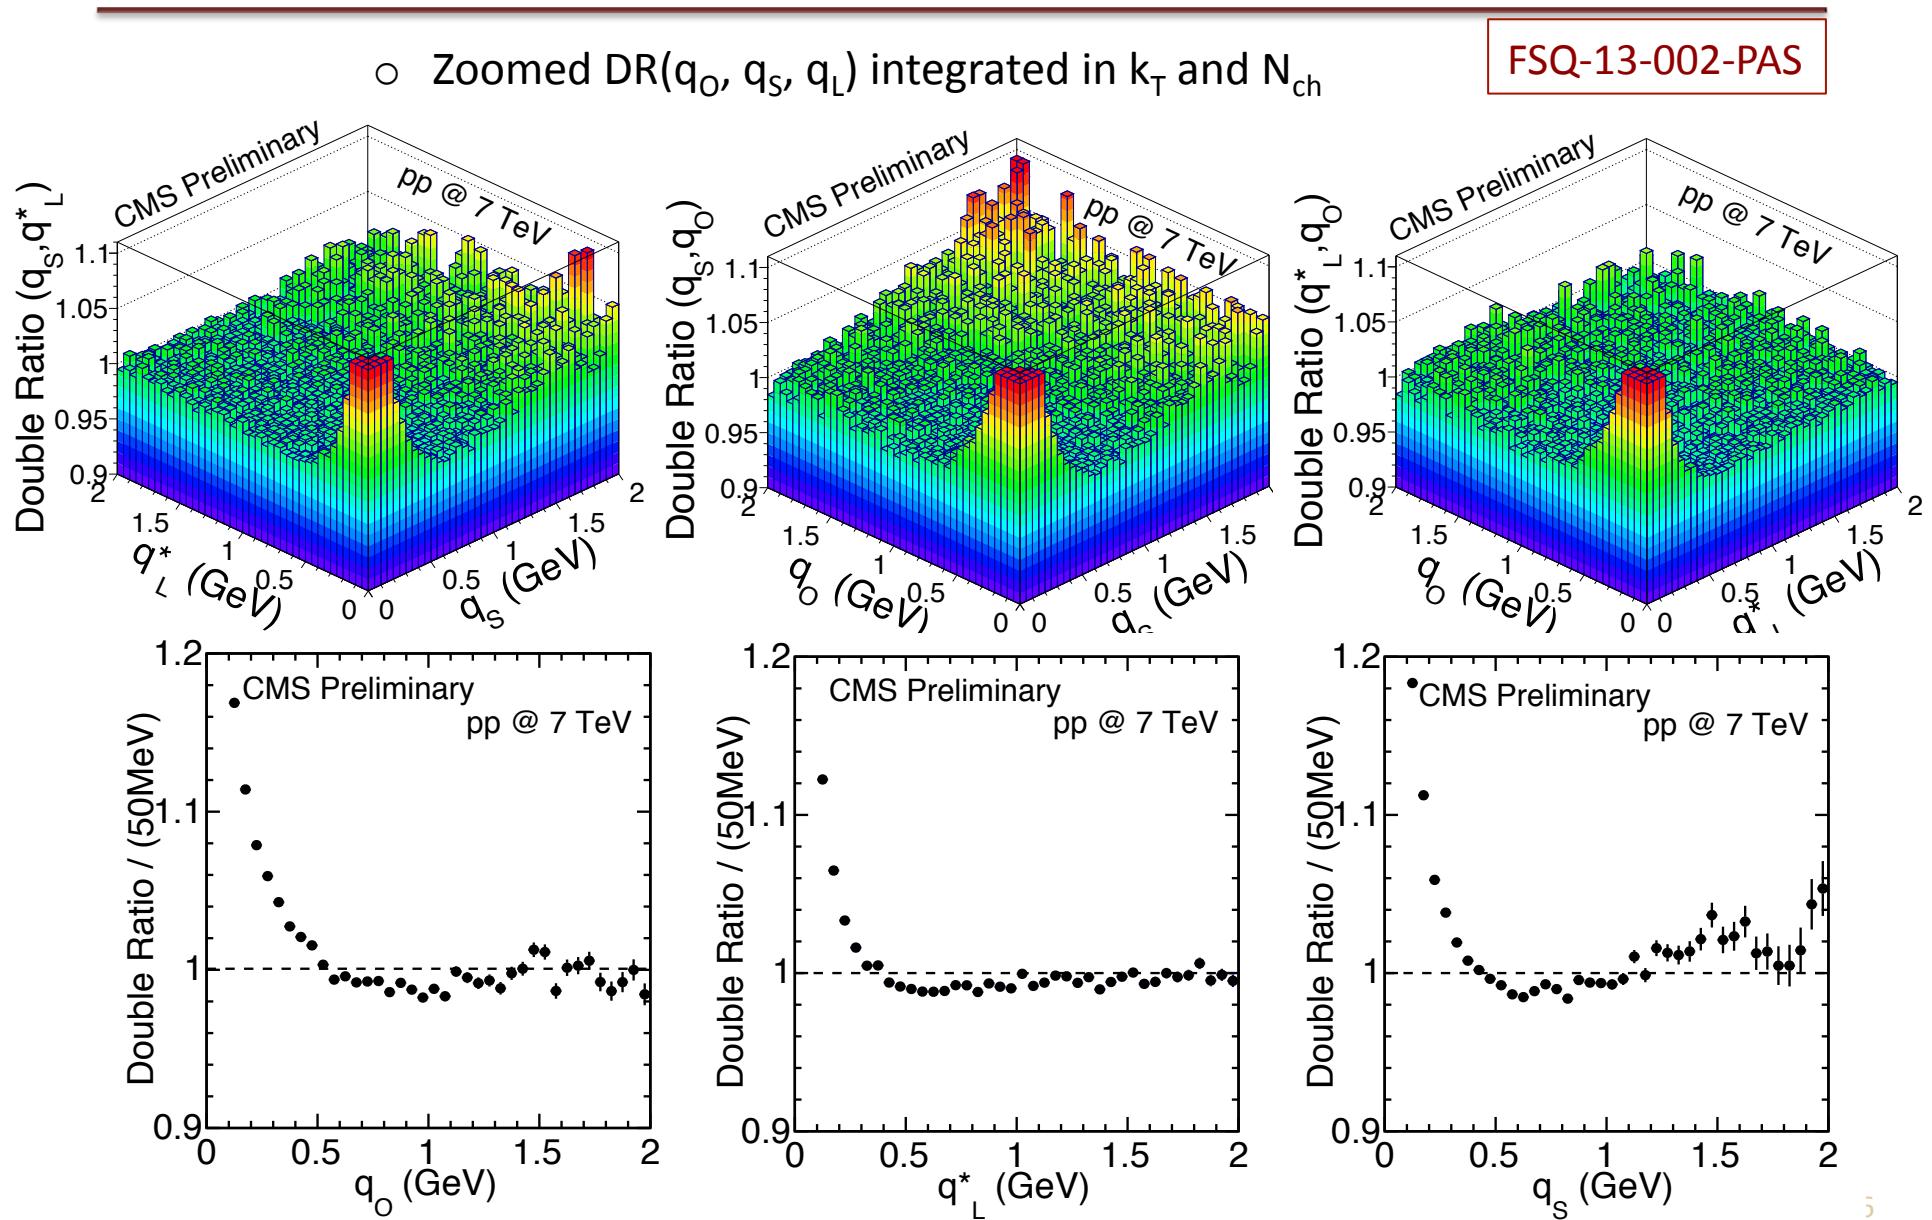

- Fits: Gaussian, *stretched* (Lévy: $a=1$) and simple exponential
 - Radius parameters R_O , R_S , $R_L^{(*)}$ in CM frame and LCMS (stretched exp.)
 - R_O , R_S , R_L (k_T integrate) ↗ as N_{ch} ↗ in both frames and all three fit functions
 - R_O , R_S , R_L (N_{ch} integrate) vs. k_T :
 - $R_S \rightarrow$ almost insensitive to N_{ch}
 - R_O , $R_L \rightarrow$ decreases moderately with k_T (more easily seen in LCMS)
 - $R_L^* > R_L$ and $R_O^* < R_O \rightarrow$ consistent with Lorentz boost from LCMS to CM frame
 - Integrated values in k_T and N_{ch} :
 - $R_S > R_O > R_L$ (in CM frame) and $R_L > R_S > R_O$ (in LCMS)
 - $\lambda^{(*)}$ intercept parameter in CM frame and LCMS (stretched exp.)
 - k_T integrated: decreases with N_{ch} for lower bins and seems to flatten out for higher N_{ch} (4 bins only)
 - N_{ch} integrated: practically insensitive to k_T

Comparing $R_L^{(*)}$ fit parameter in 2-D and 3-D

- Longitudinal fit parameters should be the similar in 2-D and 3-D
 - indeed, R_L and R_L^* lengths of homogeneity → close values
 - increase with N_{ch} and scales in energy, similar to the 1-D case

The anticorrelation in 3-D $DR(q_O, q_S, q_L)$ - LCMS

Summary and Conclusions

Summary and Conclusions

- Fits: Gaussian, *stretched* (Lévy: $a=1$) and simple exponential
- Measurements in two reference frames
 - CM frame → closer to previous two BEC from CMS, for extending to 2-D and 3D
 - requires additional cross-term (in $q_T q_L$ and in $q_O q_L$)
 - interesting observations when comparing results to those in the LCMS
 - LCMS frame → $k_L = (k_1 + k_2)/2 = 0$ (no cross-term) → comparisons
- Interesting results in 1-D, 2-D, 3D:
 - Radii fit parameters increase with multiplicity, decrease with k_T (1D, 2D, 3D)
 - $\lambda^{(*)}$: 1D → ↘ as N_{ch} , k_T ↗; 2D: ↘ as N_{ch} ↗, almost flat as k_T ; 3D: ↘ as N_{ch} ↗
(lower q_O, q_S, q_L) then flattens down; almost insensitive to k_T
 - 2D: integrated values in k_T, N_{ch} : $R^*_L > R_L$; $R^*_L > R_T$ (in LCMS)
 - $R_S > R_O > R_L$ (in CM frame) and $R_L > R_S > R_O$ (in LCMS)

Summary and Conclusions

- Anticorrelation (dip structure) [already reported in JHEP05, 029 (2011)]
 - confirmed in 1-D in pp collisions at 2.76 TeV (and higher statist. results at 7TeV)
 - present in 2-D (q_T, q_L) and 3-D (q_S, q_L, q_O) and seems sensitive to N_{ch} and k_T
 - (speculation) [○ interesting to quantify: could be related to small system behavior of the protons?
 - comparisons to models in 1D, 2D and 3D (τ model, finite size π , ...) → result ?

– Thank you!
