## Charged $\rho$ condensation in magnetic fields

Thursday 7 August 2014 14:20 (20 minutes)

The charged vector  $\rho$  meson in the presence of external magnetic fields has been in- vestigated in the framework of the Nambu–Jona-Lasinio model. The self-energy of the  $\rho$  meson contains the quark-loop contribution, i.e. the leading order contribution in 1/Nc expansion. The charged  $\rho$  meson mass is investigated numerically as a function of the magnetic field at zero temperature. It is found that the charged  $\rho$  meson mass decreases as the magnetic field increases and drops to zero at a critical magnetic field, which is found to be much lower than the value predicted by a point-like vector meson. The charged vec- tor meson condensation, i.e. the electromagnetic superconductor is induced in the QCD vacuum above the critical magnetic field.
