

### MPS aspects of the Warm Magnet Interlock System Commissioning (post LS1) LHC-OP-MPS-0010

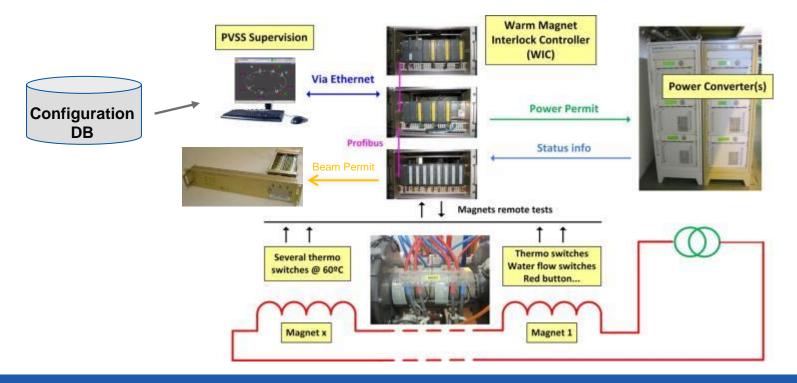

M.Zerlauth, P.Dahlen, R.Mompo, I.Romera TE-MPE-MS

## WIC installation – generic solution

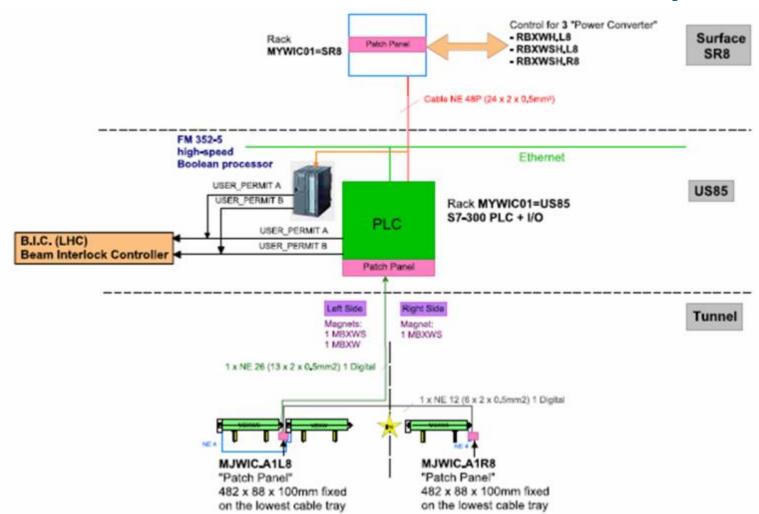

Standardized interlock system for normal conducting magnets based on Programmable Logic Controllers (PLC):

- Collects inputs from thermo-switches, flow switches and internal PC faults
- Provides Permits to the power converter and beam interlock system

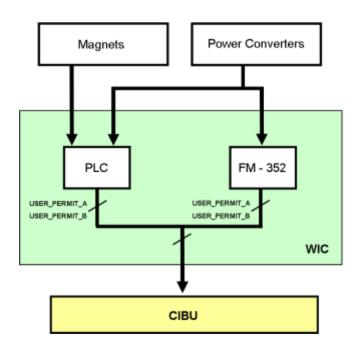

### WIC installation – LHC example

### WIC installation – Beam Dump Request

- LHC WIC based on Safety PLCs
  - Cycle time ~ 100ms
- Standard User Interface with BIS (redundant channels)
- Magnet Over temperature: Non-time critical, system generates beam dump request 1-2 sec BEFORE sending Fast Abort command to the power converter
- (Internal) power Converter failures: Immediate switch OFF, beams need to be dumped as quickly as possible
  - Fast Boolean Processor (FM352) in // to PLC, reducing delay to a few 10µsec

## **MPS** tests

#### Magnet Inputs

Test	Action	Group(s) Responsible
1 N*	Test beam dump triggered by over-temperature in a magnet.         Circuit by circuit (for every magnet) connected to the WIC:         • Verify that all Power Converters are without Fault and that no CMD_FABORT_WIC command is sent         • Verify USER_PERMIT TO BIS is OK         • Enable signal to simulate an over temperature in the magnet (CMD_MAG_OVERTEMP_TEST)         • Check that ST_MAG_OVERTEMP signal for this magnet are removed and that the power converter receives a CMD_FABORT_WIC for a few seconds         • Check that USER_PERMIT TO BIS has been removed BEFORE the power permit of the power converter is removed	
	<ul> <li>Validate the according trigger of the WIC event in the BIS history buffer and determine the time delays (for both the A and B beam permit channels).</li> <li>Validate that the output of the FM352 stays TRUE during the test</li> </ul>	

\* Modified repetition from 'S' - Shutdown to 'N' - Never (i.e. only after long shutdowns)
→ Could be increased once fully integrated in ACCTEST

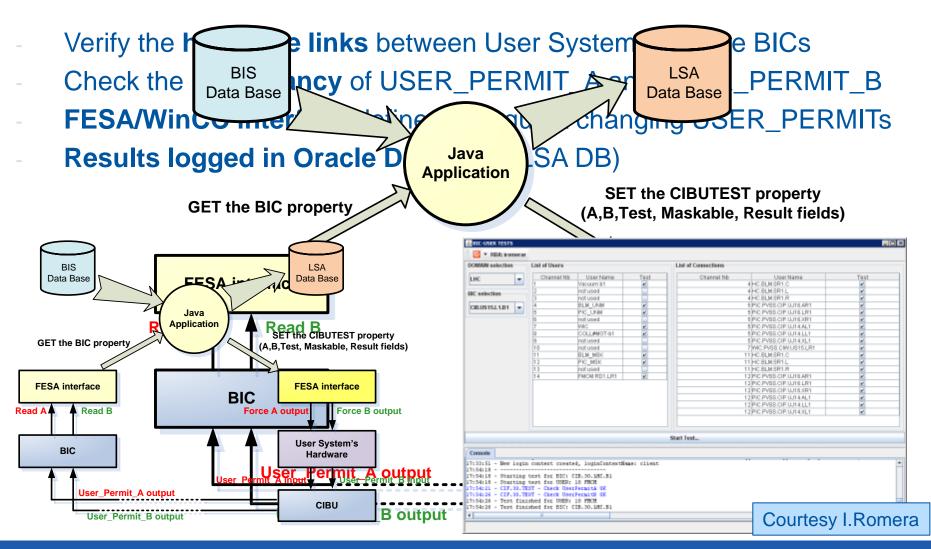

#### **Power Converter Inputs**

Test		Action	Group(s) Responsible
2	N*	<ul> <li>Test beam dump triggered by PC event: <u>For every Power Converter connected to the WIC:</u> <ul> <li>Verify that:</li> <li>All Power Converters are without Fault and that no CMD_FABORT_WIC command is sent</li> <li>All ST_FAILURE_WIC signals are OK</li> <li>USER_PERMIT TO BIS is OK</li> </ul> </li> <li>Send CMD_FABORT_WIC to the PC</li> <li>Check that: <ul> <li>CMD_FABORT_WIC has been received by the converter</li> <li>ST_FAILURE_WIC is NOT OK</li> <li>USER_PERMIT TO BIS has been removed</li> </ul> </li> <li>Validate the according trigger of the WIC event in the BIS history buffer and determine the time delays (for both the A and B beam permit channels).</li> <li>Validate that the output of the FM352 changes to FALSE when the powering failure is triggered. Validate that the time response of the FM352 is as expected in the order of a few us.</li> </ul>	TE/MPE TE/EPC
3	N*	Confirm that an operator can set the WIC USER_PERMIT to FALSE.  • Verify that:  • All Power Converters are without Fault and that no CMD_FABORT_WIC command is sent  • All ST_FAILURE_WIC signals are OK  • USER_PERMIT TO BIS is removed upon the operator request	TE/MPE

#### SCADA commands

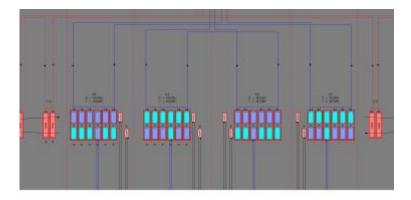

### Stand alone tests with User Systems

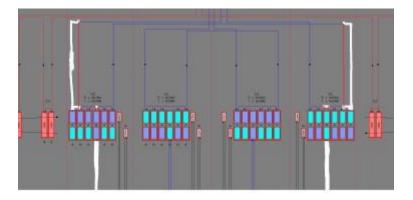

### LS1 changes 1/2

- R2E: System in point 8 moves in database from US85 to UA83 (physical relocation already done during run1)
- Removal of temporary nc corrector in L8 following re-establishing the sc corrector circuit RCBCHS5.L8B1 -> Remove from configuration
- Standardisation of channel allocation on few instances (transparent for operation but implying minor HW in IR6 and SW modifications in all systems)
- Removal of last MQWA & conversion of MQWB into MWQA in C5L7 and C5R7 (to make room for additional mask to protect nc magnets from radiation) ECR 1321045?!

- Deployment of WIC solution in injectors requires modification of generic code base to provide additional operational flexibility
- Required modifications detailed in ECR (waiting circulation by Samy)
- Updated version of code ready for deployment latest in September 2014 (EN/ICE)
- Initial Powering Tests during HWC can be performed with existing version
- Final re-commissioning to take place ahead of beam commissioning (no tunnel access needed anymore)

## SW configuration process

- Issue is with implicit linking of actions in generic PLC code base
- Program initially designed for LHC where all circuits critical for beam operation, hence a FastPA and Beam Dump are simultaneously required
  - Inputs share (undistinguishable memory area) + single configuration matrix
- Modification will separate actions and provide full flexibility for definition of dump requests and Fast Power Aborts for each input signal

# Conclusions

- MPS document updated and ready for new approval round, only minor changes to procedure
- Commissioning through automated sequence/point
- Few changes remain to be confirmed (RQ5 in IR7)
- Issue with generic code base not vital to be applied in LHC if time allows will push new version before beam commissioning
