*21st International Conference on Computing in High Energy Physics*

*13th April 2015*

---

# Outline

---

- What are Containers?
  - The Container ecosystem
  - Container deployment and management
  - HEP benchmarking
  - Conclusions
-

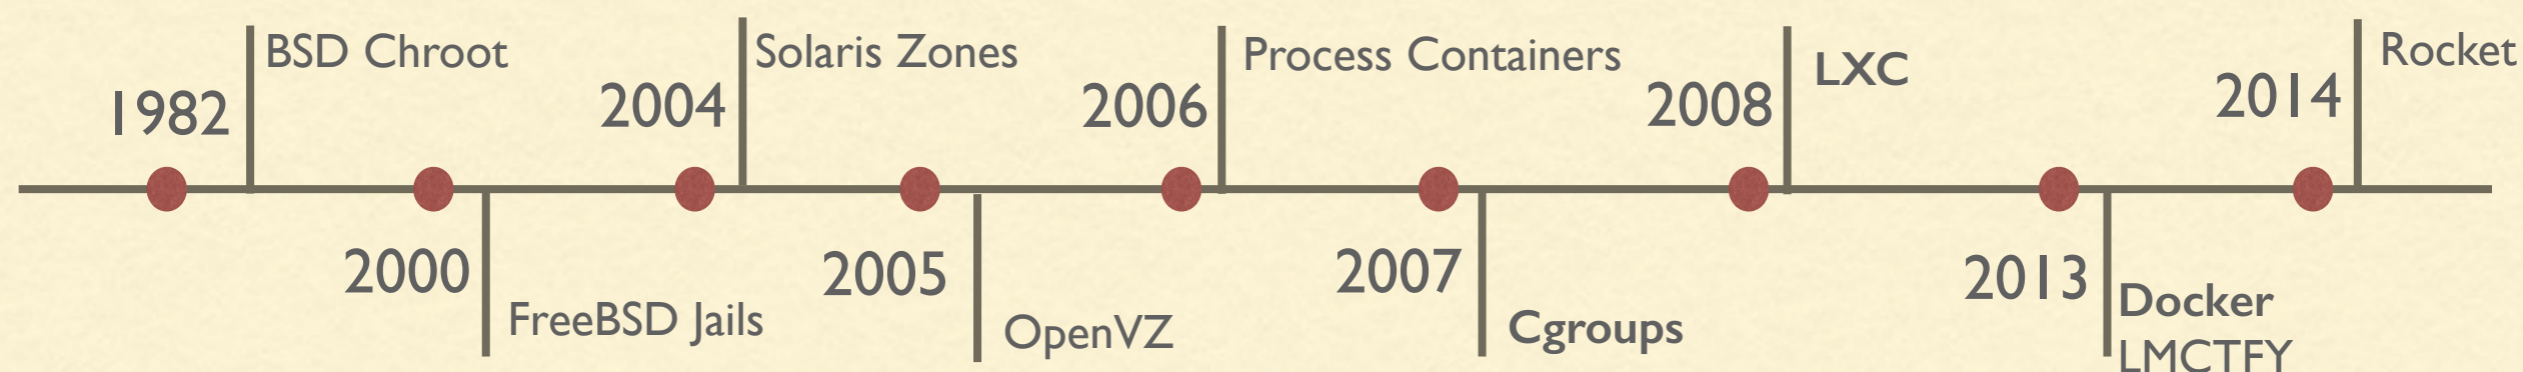

# Containerisation

- Containerisation is a form of **OS level virtualisation**
- The Linux kernel hosts multiple partitioned user-land instances (Virtual Environments)
- Accomplished through separate *namespaces* for filesystem mounts, network, processes and users
- Backing storage can be Copy-on-Write or a union filesystem (UnionFS/AUFS)

## Linux Container

### Containers Timeline

# Comparison with Virtual Machines

## ■ Pros:

- OS independent
- Security Model
- Live migration
- Mature ecosystem

## ■ Cons:

- Full system image
- Slow startup and build
- Memory consumption
- Opaque to host

Virtual  
Machine

## ■ Pros:

- Low barrier of entry
- Fast Instantiation
- Native Performance
- Deployment Flexibility

## ■ Cons:

- Restricted to Linux
- Shared Kernel
- Security Model
- Young Ecosystem

Linux  
Container

# The Container Ecosystem

---

- There is a growing ecosystem of tools and services to deploy, manage and orchestrate containers
- The most popular container application platform is **Docker**

LXC - tools for container lifecycle management

Application virtualisation engine based on containers (*LXC, libcontainer*)

Kubernetes - Docker container orchestration system for large scale application deployment

Open source minimal OS specifically designed to host and cluster application containers

Tools for working with containers focusing on the *Application Container Image* (an open standard for container formats)

# Openstack Container Management

- Explored the readiness of OpenStack to natively support the management of containers
- Enables easy integration with cloud infrastructure available in WLCG
- A Docker driver is not in the current Openstack release (Juno)
  - Manually install driver: <https://wiki.openstack.org/wiki/Docker>

```
# docker pull cern/slc6-lite  
# docker save cern/slc6-lite | glance image-create --is-public=True --container-format=docker  
--disk-format=raw --name cern/slc6-lite
```

Virtual Machine

Container

The screenshot shows the OpenStack dashboard interface. The left sidebar contains navigation options: Project (Compute), Overview, Instances, Volumes, Images (highlighted), Access & Security, Network, Object Store, Admin, and Identity. The main content area is titled 'Images' and displays a table of image assets. The table has columns for Image Name, Type, Status, Public, Protected, Format, Size, and Actions. The following table represents the data shown in the screenshot:

Image Name	Type	Status	Public	Protected	Format	Size	Actions
tutum/wordpress	Image	Active	Yes	No	RAW	493.7 MB	Launch
cern/slc6-lite	Image	Active	Yes	No	RAW	132.5 MB	Launch
uCERN VM 1.18-13	Image	Active	Yes	No	RAW	20.0 MB	Launch
Fedora 21	Image	Active	Yes	No	QCOW2	151.1 MB	Launch
Cirros 0.3.3	Image	Active	Yes	No	QCOW2	12.6 MB	Launch
Fedora 21	Image	Deleted	Yes	No	QCOW2	0 bytes	

At the bottom of the table, it says 'Displaying 6 items'. The 'cern/slc6-lite' and 'Fedora 21' rows are highlighted with red boxes. An arrow points from the 'Container' label to the 'cern/slc6-lite' row, and another arrow points from the 'Virtual Machine' label to the 'Fedora 21' row.

---

# HEP Containers

---

## Container comparison with CERNVM image

- Pull base CentOS 6 image from Docker registry
- CVMFS mounted as an external volume
- Increase storage in the container for datasets and job output

## CVMFS integration

- CVMFS requires root-privileges for FUSE interaction.
  - *Either* run a **privileged** container and export the CVMFS volume to other containers
    - Security implications
  - *Or* export the CVMFS volume from the host
    - Not a flexible hypervisor solution
    - Can lead to issues with other container management tools (CoreOS, Project Atomic)
-

---

# HEP Workload Performance Testing

---

## Motivation

- Do containers offer native performance for realistic HEP-based workload?
- What is the performance penalty for using Virtual Machines over bare metal (and containers)?

## Workload types

- HEPSPEC benchmark
  - Geant4 Monte Carlo Simulation
  - Event Reconstruction
  - Monte Carlo event generation
-

# HEP Workload Performance Testing (2)

## Test Platform

- Run each HEP workload type on two testbed servers; one containing an Intel Xeon processor and the other an Avoton processor
  - **Avoton:** Low power Atom-based 22nm SoC device
- Run each workload type on bare metal, in a virtual machine (KVM) and in a container (Docker)
  - Adapted a  $\mu$ CERNVM image for testing purposes
  - Tested both a RAW image file and a LVM partition as VM backing storage

- SuperMicro Twin Squared
  - 2 x E5-2650 v2 2.6GHz
    - 16 cores (32 Hyper threaded)
  - 64 GB RAM
  - 2 x 500GB 7200rpm SATA 6.0

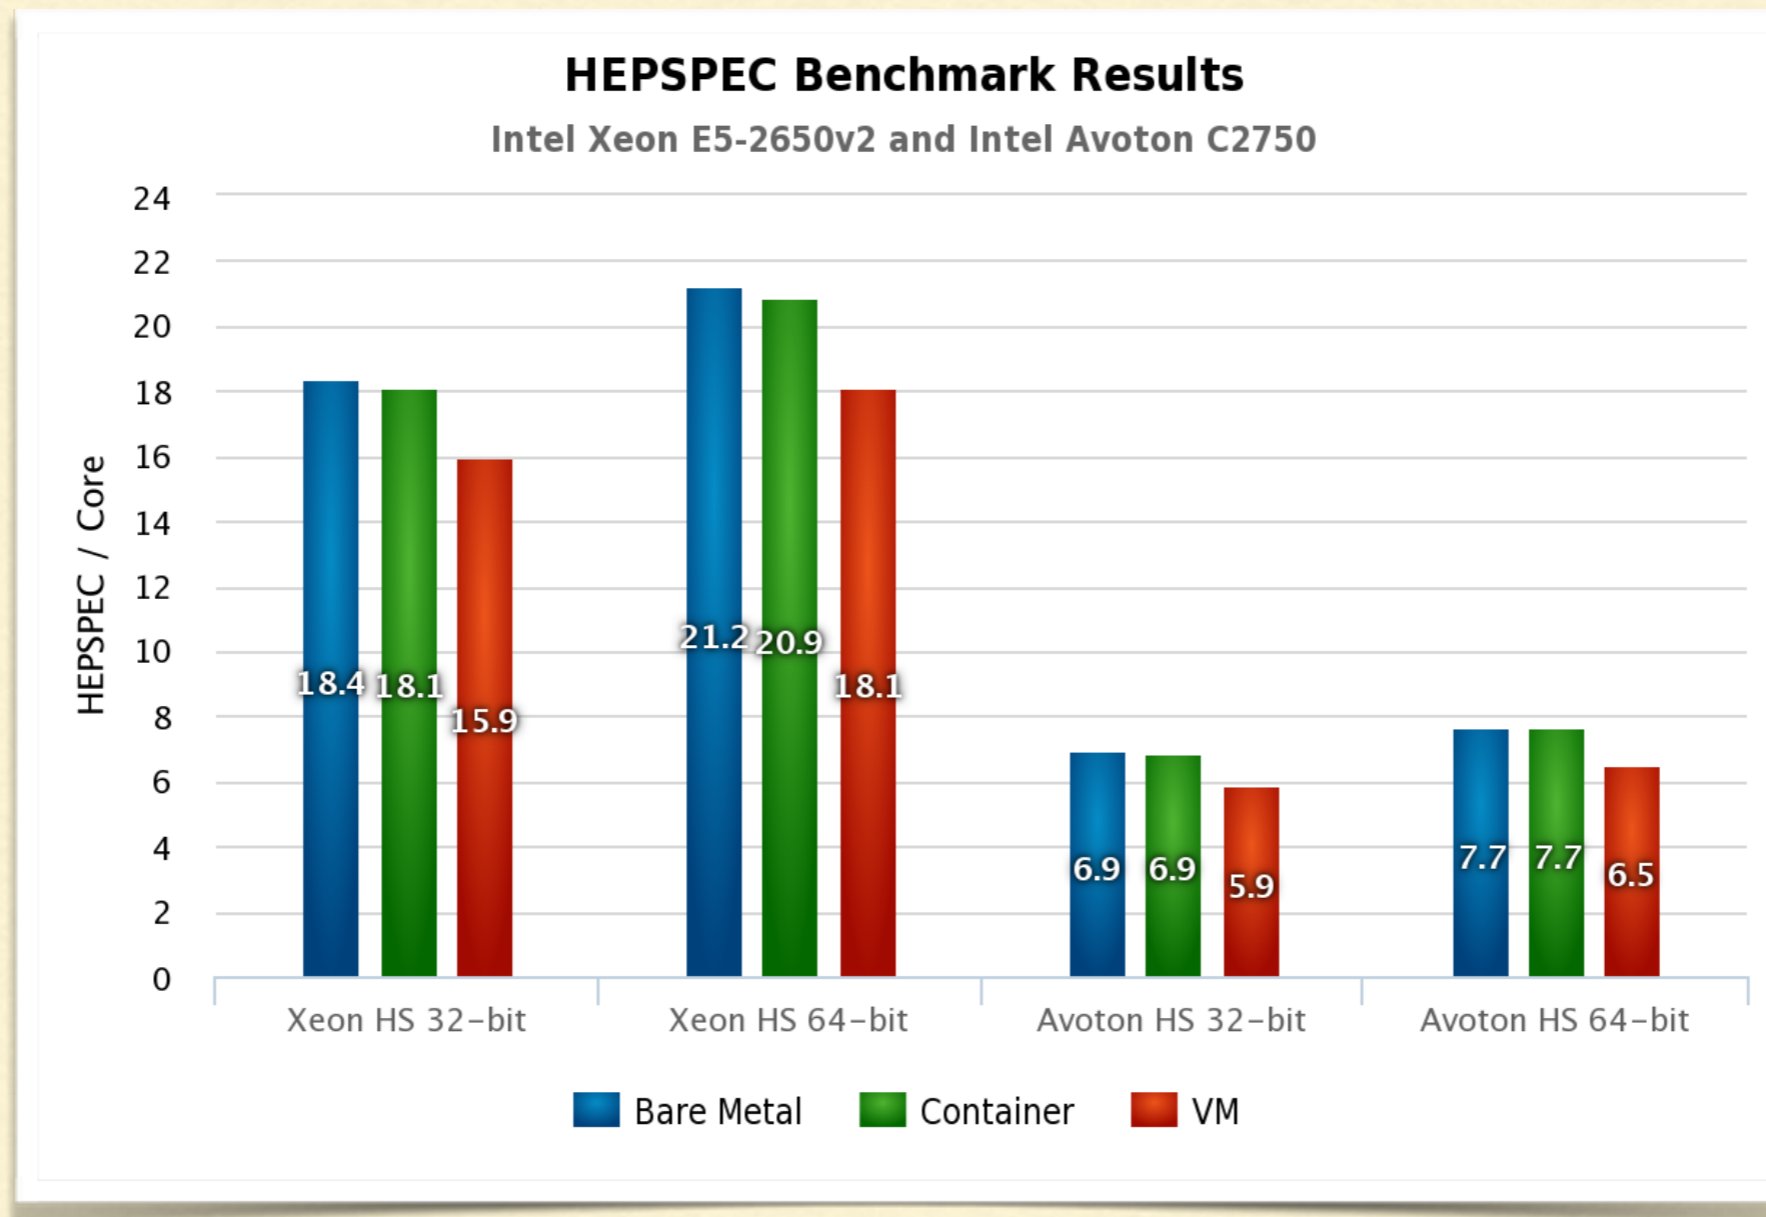

- DELL FX2 FM120 Avoton
  - Intel C2750 2.4Ghz
    - 8 cores (Avoton Atom CPU)
  - 16GB RAM
  - 80GB SSD

## Test Patterns

- Run each test multiple times to validate performance and timing consistency
- Run single core and  $N$  (= number of cores) simultaneous workload instances

# HEPSPEC Benchmark Results

- Containers are within 1% of “native” HEPSPec performance
- Benchmark score for VMs are **14.7%** less for the Xeon and **15.3%** less for the Avoton compared to the native HEPSPec (64-bit) score

# MC Simulation Results

- Focus on relative performance in event processing loop
- CPU time/event (as reported by application) is averaged over 40 events

- Containers demonstrate near-native performance
- Single process MC simulation timing performance is **13.4%** lower for the Xeon and **26.4%** lower for the Avoton
- For 16 (8) simultaneous processes: VM is **24.7%** lower for Xeon (**32.5%** lower for Avoton)

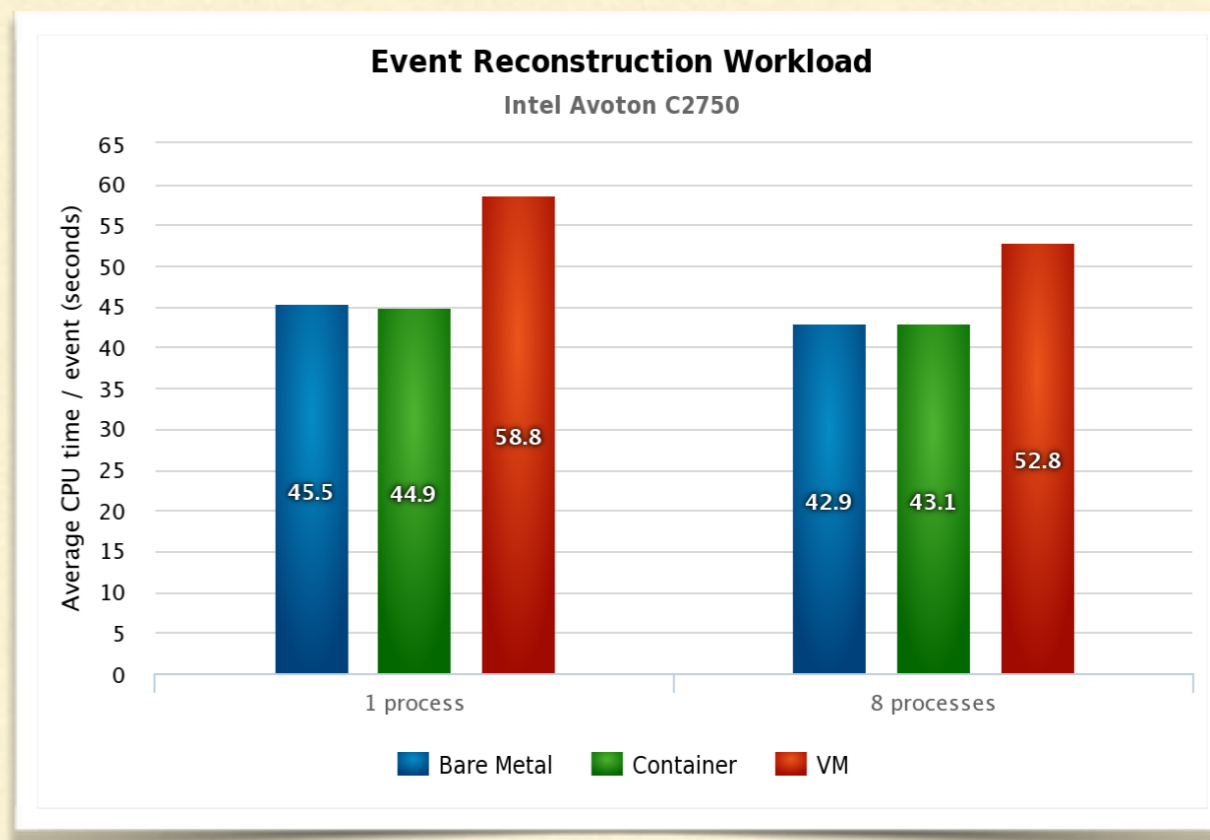

# Event Generation and Reconstruction Results

## Event Generation

- Measured total time taken to generate large sample of  $Z\mu\mu$  events
- VMS lose only 5% performance compared to bare metal and containers

## Event Reconstruction

- CPU time/event averaged over 50 events
- VMs show 22.6% performance drop for a single process, 18.8% for 8 simultaneous processes

---

# Conclusions

---

- Containers are a compelling alternative to whole system virtualisation
- The performance of containers for HEP workloads are similar (if not the same) as native execution
- Virtual Machines observed to give a reduction in performance of 15-20% on HEP workloads
  - Caveat: VMs could be tuned to give better performance

## Future Work

- Potential deployment of containers on existing HEP cloud resources
  - Does HEP lend itself to the single application model preferred by Docker?
    - Consider: middleware deployment, distributed computing components (e.g pilots)
  - Effort has already started (see next presentation!)
-

---

# Any Questions?
