CONCLUSION & PERSPECTIVES

Scientific objective: in-vivo ion range verification

Hadrontherapy: ion therapy

- ⇒ Target volume: dose maximised
- ⇒ Organ at risks: dose minimised
→ prevent side effects

Scientific objective: in-vivo ion range verification

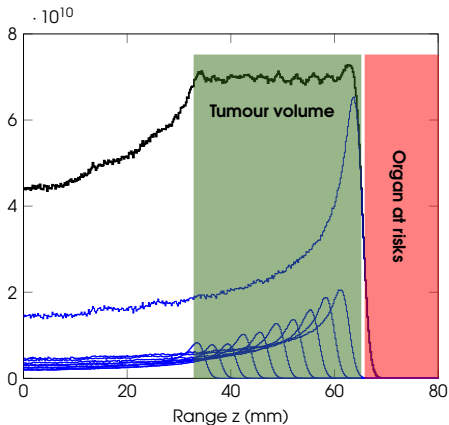

Hadrontherapy: ion therapy

- ⇒ Target volume: dose maximised
- ⇒ Organ at risks: dose minimised
→ prevent side effects
- ⇒ ion beams, e.g. protons will interact through matter:
 - ≫ increasing **energy deposition** until reach a **maximum**
 - ≫ **finite range**

Scientific objective: in-vivo ion range verification

- ⇒ Target volume: dose maximised
- ⇒ Organ at risks: dose minimised
→ prevent side effects
- ⇒ ion beams, e.g. protons will interact through matter:
 - ≫ increasing **energy deposition** until reach a **maximum**
 - ≫ **finite range**

⇒ range monitoring is a key issue of hadrontherapy treatments

Scientific objective: in-vivo ion range verification

Range uncertainties

- ⇒ <5 mm uncertainties
- ⇒ systematic uncertainties: could be reduced as much as possible
- ⇒ random uncertainties: could not be prevented without any beam delivery monitoring

Scientific objective: in-vivo ion range verification

Range monitoring: detection of secondary particles

GEANT4 simulation: ^{12}C 163 MeV.u $^{-1}$ on PMMA target

⇒ Induced β^+ activity measurements during irradiation:

- ⇒ annihilation photon pairs → good events ☺
- ⇒ prompt particles (mainly nuclear γ → bad events ☹)

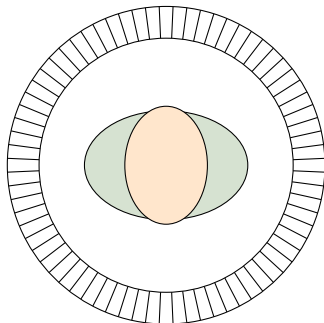

⇒ $\beta^+ \rightarrow 2 \times 511 \text{ keV } \gamma$ (induced radioactivity)

⇒ ^{10}C ($T_{1/2} = 20 \text{ s}$)

⇒ ^{11}C ($T_{1/2} = 20 \text{ min}$)

⇒ ^{15}O ($T_{1/2} = 2 \text{ min}$)

⇒ prompt γ : nuclear γ (1,10 MeV)

What we would like: waveform digitisation

- ⇒ Acquisitions during irradiation is **very noisy**: need for **random coincidences rejection**
- ⇒ Improve trigger selectivity: data sampling allows to **re-process and refine** trigger off-line (not possible with TDC+QDC)
- ⇒ Read-out electronics should be **generic** for different photosensors

What we have

- ⇒ Since 2002, different **read-out electronics** based on **switched capacitor array** technology have been developed at LPC for physics experiments:
 - **ARS16 board** based on ARS0 chip ¹: 16 channels, buffer depth=128, $F_{samp}=300$ MHz-1 GHz, ADC(12 bits): 1 MHz
 - **ASM board** based on DRS4 chip ²: 24 channels, buffer depth=1024, $F_{samp}=500$ MHz-6 GHz, ADC(12 bits): 33 MHz
- ⇒ 1 small solid angle detector has been developed:
 - **2×20 channels**: 1 channel = APD S 8664-55 (Hamamatsu) coupled to LYSO crystal ($5\times 5\times 22$ mm³)
- ⇒ 1 larger solid angle detector is under development:
 - **2×120 channels**: 1 channel = 1/2 inch head on PMT coupled to LYSO crystal ($13\times 13\times 15$ mm³)

USE OF ASM BOARDS

CONCLUSION & PERSPECTIVES

Experiments

- ⇒ We have conducted several experiments on proton and carbon beams
- ⇒ GANIL³, research facility ⇒ **75 MeV.u⁻¹ carbon beams**
- ⇒ CPO⁴, clinical facility ⇒ **86 MeV proton beams**
- ⇒ **main problem**: how to **discriminate**, during *in-beam* acquisitions, annihilation photon pairs from nuclear induced background ?
- ⇒ **main hypothesis** to deal with this issue: **nuclear background is synchronous to the beam extraction** → synchronise DAQ to the accelerator frequency

³ Grand Accélérateur National d'Ions Lourds

⁴ Centre de ProtonThérapie d'Orsay

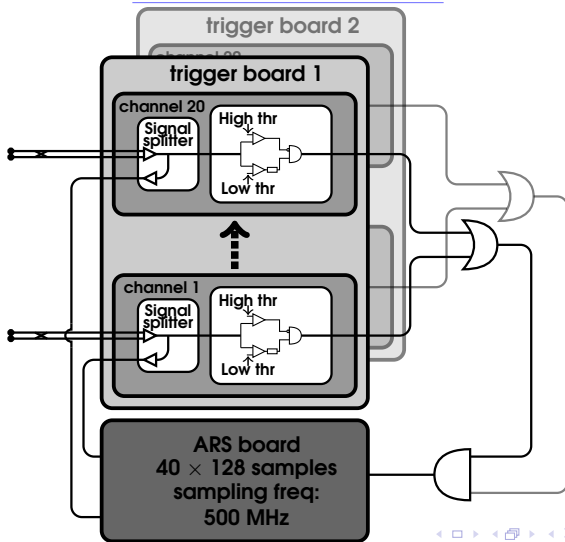

Experiments with small solid detector (APD-based)

- ⇒ Custom made trigger boards: both heads operated in coincidence
- ⇒ Read-out electronics: ARS16 boards, $F_{\text{samp}}=500$ MHz
- ⇒ Experiments done at GANIL:
 - ≫ ^{13}C 75 MeV/n
 - ≫ **continuous extraction**
 - ≫ cyclotron frequency: **12 MHz** → **1 bunch every ~80 ns**
- ⇒ Experiments done at CPO:
 - ≫ **p 86 MeV**
 - ≫ **continuous extraction modulated**: 50 ms extraction + 50 ms pause
 - ≫ cyclotron frequency: **106 MHz** → **1 bunch every ~9 ns**

Experiment with the APD based detector

Trigger block diagram

Experiment with the APD based detector

GANIL experiment results

- ⇒ GANIL experiment:
- ⇒ **synchr**: $\Delta t_{\gamma\gamma-RF} \in [30\text{ns}; 50\text{ns}]$
- ⇒ **asynchr**: $\Delta t_{\gamma\gamma-RF} < 30\text{ns}; \Delta t_{\gamma\gamma-RF} > 50\text{ns}$
- ⇒ **after irr**: after irradiation
- ⇒ **Nuclear induced background well synchronised to the beam extraction**

CPO experiment results

- ⇒ CPO experiment:
- ⇒ **No time correlation visible**
- ⇒ **Coincidence Resolving Time (CRT) improvement → 5.4 ns (FWHM) with this setup**
- ⇒ **use of faster photodetector than APD → PMT works well**
- ⇒ **Need for finding another selection criterion when cyclotron frequency is too high (~ 100 MHz)**

Use of PMT to improve CRT

- ⇒ Use of PMT from an old HR⁺ PET system
- ⇒ Better timing resolution: 1 ns (FWHM)
 - ≫ **LaBr₃ (5%Ce) crystal** (12.7×12.7 mm³) coupled to a PMT Hamamatsu H6533 against **LYSO crystal** (13×13×15 mm³) coupled to a HR⁺ PMT
 - ≫ acquisitions with LecroyTM oscilloscope (6050 A): 500 MHz analog bandwidth, 2.5 GSPS

⇒ those PMT's seems to be good enough to build a cheap large acceptance detector dedicated to *in-vivo* particle range monitoring

On-beam test with blocks of large acceptance detector

- ⇒ Preliminary tests with a pair of 4 channels, PMT+LYSO crystal ($13 \times 13 \times 15 \text{ mm}^3$) has been made at CPO facility

- ⇒ Both blocks are operated in coincidence and the 8 channels are read-out by ARS16 boards
- ⇒ Two acquisitions have been done at two different beam intensities: low intensity ($\sim 2 \cdot 10^7 \text{ p.s}^{-1}$) and higher intensity ($\sim 7 \cdot 10^8 \text{ p.s}^{-1}$)

Preliminary results on beam

Preliminary *in-beam* results

⇒ at low intensity, annihilation photon pairs are **easily detected**

⇒ **CRT = 3 ns (FWHM)**

⇒ CRT should be better with faster sampling

⇒ at higher intensity → high dead time

⇒ Nevertheless, we are able to **more efficiently extract** annihilation photon pairs during *in-beam* acquisitions

MOTIVATIONS

RETURN OF EXPERIENCE

USE OF ASM BOARDS

CONCLUSION & PERSPECTIVES

Use of ASM boards

- ⇒ **Analog Sampling Module (ASM)** boards, based on DRS4 chip, have been developed at LPC (cf. talk M.Magne)
- ⇒ able to sample analog waveforms **up to 6 GHz**
- ⇒ well adapted to read-out **fast photodetectors** such as MCP-PMT, SiPM, dSiPM: at least 5 samples on the rising edge if rising time is ~ 1 ns
- ⇒ should **improve CRT** of our PMT-based detector
- ⇒ these boards are also able to **generate a first level trigger**
- ⇒ **scalable system** to read-out several hundreds of channels

A 240 channels detector

A 240 channels detector

- ⇒ 2 heads: 120 channels per head
- ⇒ a channel: 1 PMT+1 LYSO crystal ($13 \times 13 \times 15 \text{ mm}^3$)
- ⇒ intern diameter: 322 mm
- ⇒ axial FOV: 188.5 mm
- ⇒ total weight: $\sim 70 \text{ kg}$
- ⇒ 12 ASM boards to read out all the 240 channels
- ⇒ DAQ μTCA

Timing resolution

- ⇒ CRT measured :**2 LYSO crystals** ($13 \times 13 \times 15$ mm³) coupled to HR⁺ PMT
- ⇒ ASM board read-out each channel: 4.1 GSPS
- ⇒ Acquisitions performed via custom made C++ program (CPU VME)
- ⇒ **CRT reached: 1.2 ns (FWHM)**

Outline

MOTIVATIONS

RETURN OF EXPERIENCE

USE OF ASM BOARDS

CONCLUSION & PERSPECTIVES

Conclusion

- ⇒ We would like to **monitor ion range during treatment** by measuring induced β^+ activity
- ⇒ We need to **extract annihilation photon pairs** from induced nuclear background
- ⇒ Several experiments have been done on proton and carbon ion beams
- ⇒ We conclude that **extraction of good events** is possible if **timing resolution is good enough** comparing to the mean time between two ion bunches
- ⇒ A **fast sampling read-out electronics**, based on DRS4 chip, has been especially developed for this purpose
- ⇒ A **CRT of 1.2 ns (FWHM)** has been measured which should be enough to **improve** good events extraction during acquisition
- ⇒ This read-out electronics is also **well adapted** to fast photodetectors

Perspectives

- ⇒ Next step: **first in-beam** test with at least 80 channels (4 ASM boards)
 - ≫ GANIL: end of April
- ⇒ Then: *in-beam* tests with the **whole detector**: 240 channels (12 ASM boards)
 - ≫ CPO: end of May
- ⇒ Work on fast **photodetector** (MCP-PMT, 16 anodes (R10754X-01-M16, Hamamatsu) is on progress
- ⇒ For now characterisation with femtosecond laser
- ⇒ then timing measurement with ASM board
