

# Spectroscopy of onia and hadrons with open beauty in ATLAS

R Henderson (Lancaster) on behalf of the ATLAS Collaboration BEAUTY 14-18 July 2014

The ATLAS detector is a general purpose detector (GPD) with almost  $4\pi$  coverage

# ATLAS Inner Detector ID

- 2T magnetic field, coverage  $|\eta| < 2.5$
- Momentum scale:  $\sim 0.1\%$  at low energy,  $\sim 1\%$  up to  $\sim 100$  GeV
- Momentum resolution:  $\sigma/p_T = 3.8 \times 10^{-4} (\text{GeV}) \oplus 0.015$
- Primary vertex resolution:  $\sim 30 \mu\text{m}$  transverse,  $\sim 50 \mu\text{m}$  longitudinal

# The ATLAS Muon Spectrometer (MS)

- Coverage  $|\eta| < 2.7$
- Average field 0.5T
- Momentum resolution  $< 10\%$  for muons with energy  $< 1$  TeV
- **Essential for onia analyses for both trigger and offline muon identification, the track parameters coming entirely from the ID however.**

# Luminosity and Pileup

**Trigger:** The ATLAS trigger has been able efficiently to process increasing luminosity. Vital to onia and b physics is the b-physics di-muon trigger.

**Vertexing:** The ID vertex precision (shown above) can resolve the increasing number of primary vertices from increasing pileup

# B-Trigger

The ATLAS trigger system comprises of three levels

- **Level 1** : Hardware based , resistive Plate Chambers (RPC) , thin gap chambers(TGC), trigger on muons in  $|\eta| < 1.05$  and  $1.05 < |\eta| < 2.5$  respectively.
- **High-Level Trigger**: Software based, Level 2 trigger and the Event Filter (EF)

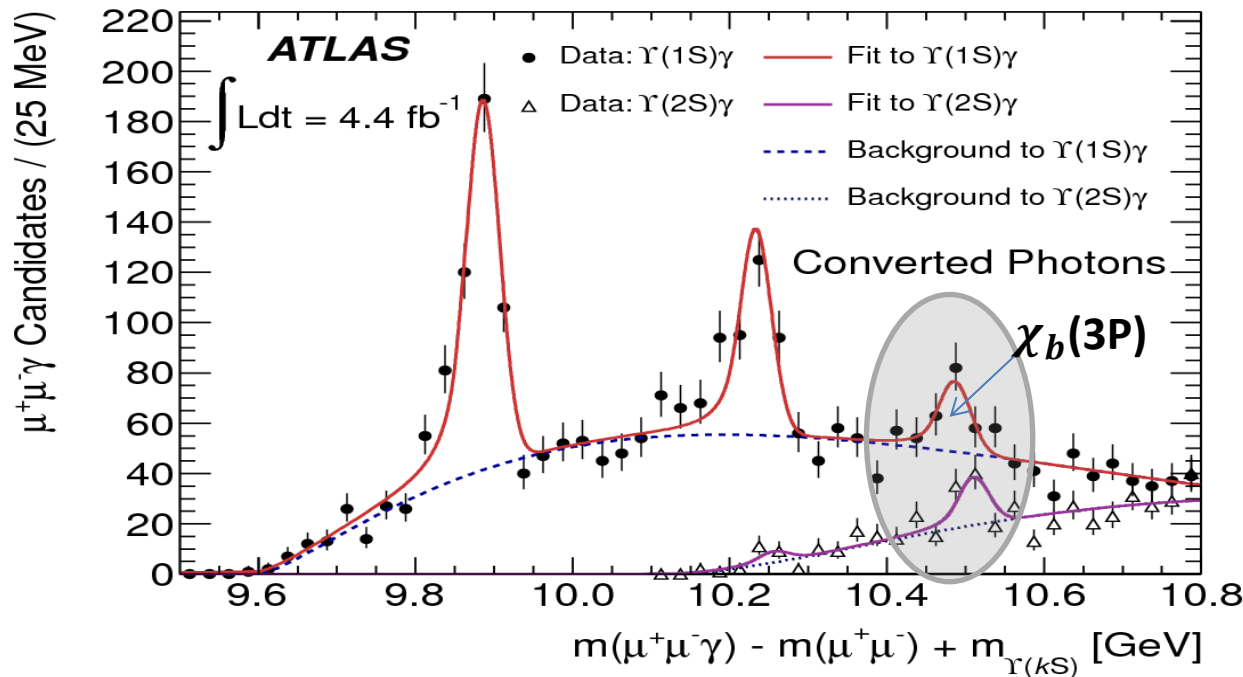

## **B-Trigger : All Onia and open B relies on this**

- One or more regions of interest (**RoI**) are identified by the Level 1 muon trigger which seed the HLT muon online reconstruction algorithms, which combine the response from both ID and MS.
- HLT  $J/\psi - \mu_1 \mu_2$  , common vertex ,  $2.5 \text{ GeV} < \text{mass} < 4.3 \text{ GeV}$  and  $p_T(\mu_1) > 6 \text{ GeV}$  ;  $p_T(\mu_2) > 4 \text{ GeV}$

**The success of this trigger means that despite increased luminosity we are able to maintain an un-prescaled  $J/\psi \rightarrow \mu\mu$  and  $\Upsilon \rightarrow \mu\mu$  trigger without any  $J/\psi$  lifetime cuts, even at full luminosity.**

# Observation of $\chi_b(nP)$ in radiative decays to $\Upsilon(1S)$ and $\Upsilon(2S)$ [2011]

[doi:10.1103/PhysRevLett.108.152001](https://doi.org/10.1103/PhysRevLett.108.152001)

$\chi_b(nP) \rightarrow \Upsilon(1S,2S) (\rightarrow \mu\mu) + \gamma (\rightarrow e^+e^-)$  (converts in ID)

# Search for an excited $B_c$ meson

The  $B_c^\pm$  has been observed in both semi-leptonic decay and hadron decay modes, but excited states have not been previously reported.

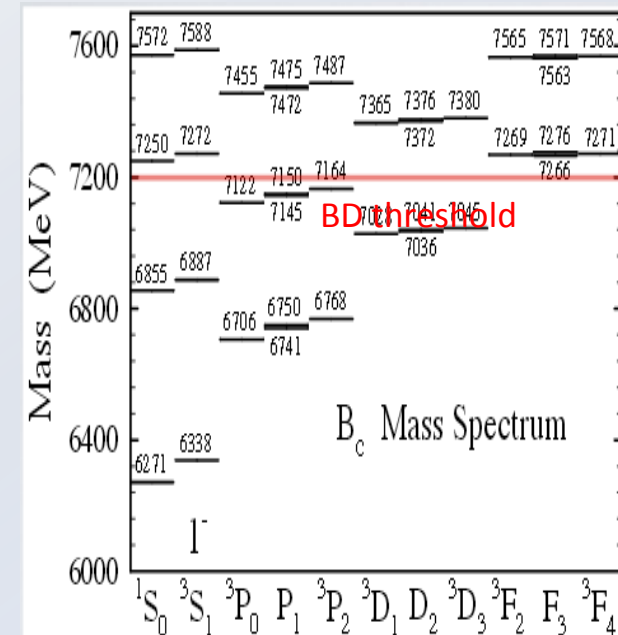

- The spectrum and properties of the  $B_c^\pm$  are predicted by NRQCD, and lattice calculations.
- Measurements of the ground and excited states will provide tests of the predictions of these models and ultimately provide the opportunity to extract information on the strong interaction potential

# Theoretical predictions for excited $B_c$ states

- **1S ground state:** both  $1^1S_0$  and  $1^3S_1$  (pseudoscalar, vector) mass difference  $\sim 20$ -70 MeV transitions via soft undetectable soft gamma.
- **2P states:** soft undetectable gamma radiation to 1S, contributes to ground state cross section.

- **2S state:**

- $B_c^{\pm*}(2S)$  predicted mass in range 6835-6917 MeV
- $B_c^{\pm*}(2S_0) \rightarrow B_c^{\pm}(1S_0) + \pi\pi$ ;
- $B_c^{\pm*}(2S_1) \rightarrow B_c^{\pm}(1S_1) + \pi\pi$ ;  $B_c^{\pm*}(1S_1) \rightarrow B_c^{\pm}(1S_0) + \nu_{\text{invisible}}$
- Mass difference  $m(2S) - m(1S) \sim 600$  MeV
- $\pi\pi$  from PV should follow  $B_c^{\pm}$  direction

# Data and MC samples

This study uses **pp collision data** samples :

- 2011 ( $\sqrt{s} = 7$  TeV) integrated luminosity  $4.9 \text{ fb}^{-1}$
- 2012 ( $\sqrt{s} = 8$  TeV) integrated luminosity  $19.2 \text{ fb}^{-1}$

## Monte Carlo data

Treated exactly as collision data

- PYTHIA 6 (tuned for LHC) is used to generate exclusive  $B_c^\pm$  channels
- PYTHIA 8 is used to generate inclusive  $J/\psi X$  channels
- The following channel samples are used to optimize the event selection criteria:  
( $J/\psi\pi$ ,  $J/\psi K$ ,  $J/\psi\rho$  ( $\rho \rightarrow \pi^0\pi^\pm$ ),  $J/\psi\mu\nu$ ,  $J/\psi\pi^0\pi$ ,  $J/\psi\pi\pi\pi$ , and  $J/\psi X$  produced from  $b\bar{b}$ )
- Difference between 7 and 8 TeV data is due to higher centre of mass energies of production and higher pileup, thus separate selection optimizations between 2011 and 2012 are required.

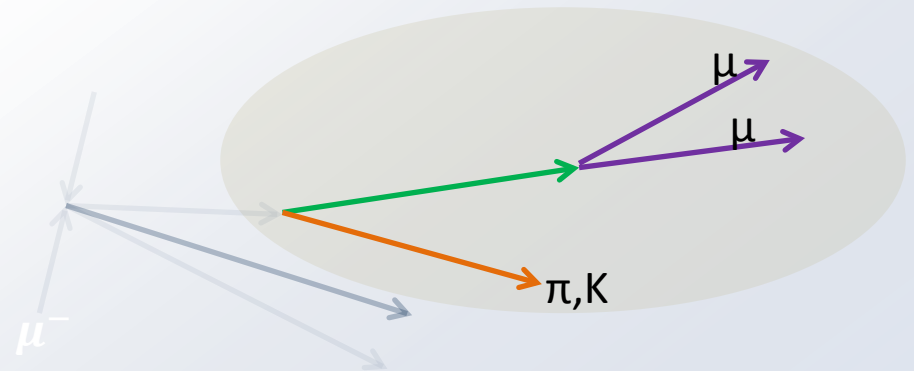

# Searching for an excited $B_c$ meson state

## Analysis overview:

- A B candidate is constructed from a  $\mu^+ \mu^-$  pair and a hadronic track using both  $\pi$  and K hypotheses forming a secondary vertex (SV).
- A  $B^*$  candidate is formed from the B candidate and two oppositely charged hadrons from the primary vertex (PV) using both  $\pi$  and K hypotheses.
- The wrong sign  $B^*$  candidates formed from same sign charged hadron from the primary vertex are also kept.

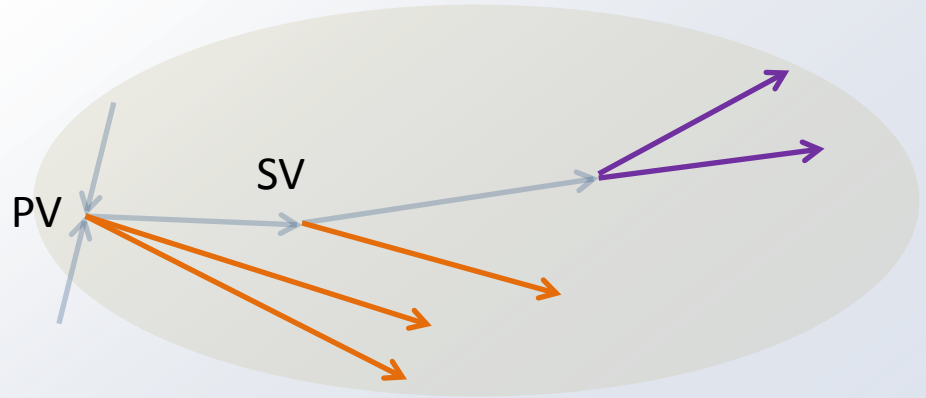

# Searching for B meson Candidates

## B candidates:

- $J/\psi \mu\mu$  vertex must have  $\chi^2 < 15$  per degree of freedom
- Hadronic tracks  $p_T > 4$  GeV
- $p_T(B) > 15$  GeV (7 TeV data);  $p_T(B) > 18$  GeV (8 TeV data).
- Cut on hadron track impact parameter quantity  $(d_o) / \sigma(d_o) > 5$  or 4.5 for 7 and 8 TeV data respectively where  $d_o$  with respect to PV.
- Cut on B vertex (sv)  
 $\chi^2 < 2$  or 1.5 per degree of freedom for 7 and 8 TeV data respectively
- Primary vertex (PV) ; 7 TeV vertex with highest  $p_T$  ; 8 TeV vertex most closely pointed at by the  $B^\pm c$  candidate

# Finding $B_c^*$ (2S) Candidates

## $B_c^*$ (2S) candidates:

- Previously found B candidates within a  $3\sigma$  mass window around the  $J/\psi$  mass are selected (this allows for the different resolutions from the Barrel and Endcap components of the ID)
- The three B candidate tracks and two hadrons from the PV are fitted simultaneously.
- The muon pair is constrained to the  $m(J/\psi)$ .
- The B and  $B^*$  candidates must have a significantly displaced vertices.
- When there are more than one  $B^*$  candidates in an event the one with the best  $\chi^2$  to the  $B_c^*$  cascade vertices fit is chosen.

$$B_C^{\pm} \rightarrow J/\psi \pi^{\pm}$$

7 TeV

8 TeV

- The solid line is the projection of the results of the unbinned maximum likelihood fit (**Gaussian plus exponential background**) to all candidates in the range 5620-6820 MeV.
- The dashed line is the projection of the background to that fit.

$$Q = m(B_C^{\pm} \pi^+ \pi^-) - m(B_C^{\pm}) - 2m(\pi_{\pm})$$

**7 TeV**  
**significance:  $3.7\sigma$**

**8 TeV**  
**significance:  $4.5\sigma$**

Lower yield due  
 to harder  $p_T$  cuts

- The solid line is the projection of the results of the unbinned maximum likelihood fit (**Gaussian plus third order polynomial**) to all candidates in the range 0-700 MeV.
- The dashed line is the projection of the background to that fit and the green shaded histogram are for the wrong pion charge combination normalised to the same yield.

# Systematics

So far all errors shown have been statistical. The systematic errors are assumed to be independent and added in quadrature giving  $\sim 4.1$  MeV

There are two dominant sources of systematic uncertainty

- Uncertainty in the  $B_c^*$  candidate ground state **largely cancelled out by the Q (mass difference) distribution**
- Uncertainty in the fitting of the mass difference distributions.
  - $B_c^*$  candidate mass systematic from procedure below 3MeV
  - Pion momentum scale relative to the B candidate 1.2 MeV
  - Residual B candidate mass uncertainty adds about 1.7 MeV

## **Q fitting systematic error estimated by**

- Varying the background model using an exponential threshold function, and higher order polynomial. **(3.4 MeV contribution)**
- Varying the fit mass range from 0-700 to 0-1500 MeV **(1.2 MeV contribution)**
- Using different models for the signal (eg. Breit-Wigner, BW convoluted with Gaussian, double Gaussian) This was found to have a negligible effect.

# $B_C^*$ signal significance

The new structure significance is evaluated by pseudo-experiment.

- Generate a large number of toy-MC experiments following the background only hypothesis  
(Using data determined parameters)
- Background shape scaled to observed number of events.
- Fit not constrained to the theoretically expected mass range ;“look elsewhere effect”.
- Significance calculated from the fraction of pseudo-experiments in which the difference  $\Delta\ln L$  with and without signal is larger than in the data.

# Conclusions

The observation of excited  $B_c^*$  state with

- $Q = 288.3 \pm 3.5 \pm 4.1$
- Corresponding to a mass of  $6842 \pm 4 \pm 5$  MeV
- With a significance of  $5.2\sigma$  for 2011 and 2012 data combined
- Consistent with predicted mass of  $B_c^*$  (2S)
- This result will help refine the details NRQCD and lattice models
