# *SDP UV Buffer in CRISP Context*

# Global UV Buffer option

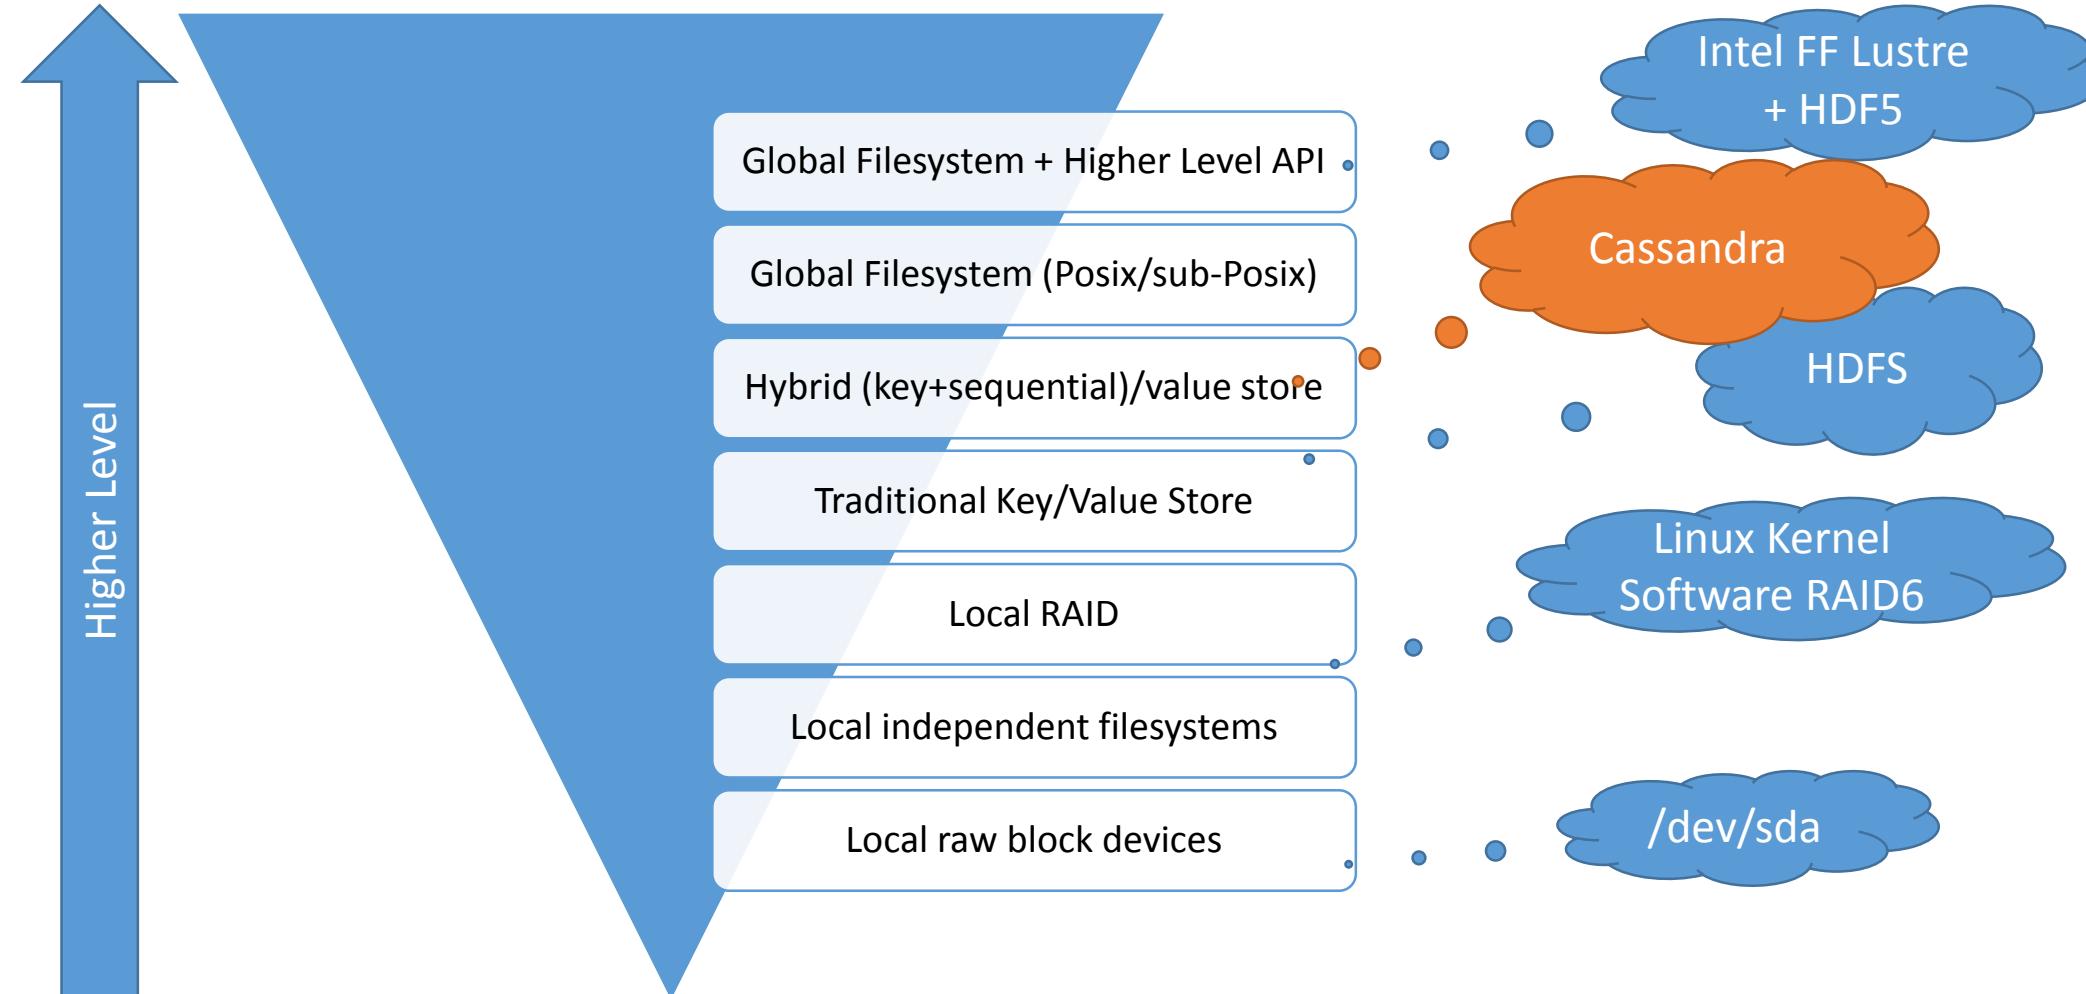

# Specifications (maximal case)

Throughput	Write: maximum case 7 Tbyte/s Read: maximum ~5 times higher
Capacity	Maximum requirement 300 Pbyte Data lifecycle ~ 12 hours
Files	Maximum $10^8$ files (one file per ten frequency channels per snapshot)
IO Computational Intensity	>250 Floating Point Operations per Byte of IO to UV Buffer
Deployment Date	Start of commissioning 2019. Science Operations 2021

# Global Filesystem Motivation

*Only one of the options being considered for SKA Science Data Processor UV Buffer*

# Options/Alternatives

# Global Filesystem is not *Required*

- But this **always** true:
  - Computation is only ever done on words in the CPU
  - Large storage systems are always made of many smaller drives
  - Global Filesystem is just a software sub-system
- Why global filesystem?
  - Simple, familiar concept
  - Simple well known, very often used API and UI
  - Combine inter-node data communication, inter-node metadata distribution, persistence, inter-node high-availability and failover mechanisms all in one subsystem
  - Off the shelf vendor solutions & open source solutions

# Global Filesystem Features revisited

## Write to File

- Make data available to any node at any subsequent time
- Redundantly distribute data on multiple nodes and disks

## Read from File

- Retrieve data from any node from arbitrary previous time
- On-the-fly recover from lost nodes and disks

## File Open For Write

- Process signals that it is doing a piece of work

## File Open For Read

- Process signals that no more work on this can be done until close

## Directory list

- What are other nodes doing?
- What have other nodes done in the past

## File Permissions

- Enforce interfaces between nodes
- Enforce interfaces between processes

# Approaching a Trade-Off Analysis

- What are the inter-node communication features we **need**?
- What do we know we can do efficiently without a global filesystem?
- What is the performance of current global filesystems in providing the features we need?
- What is the capital/op-ex cost of global-filesystem?
- What are the impacts on software development costs?

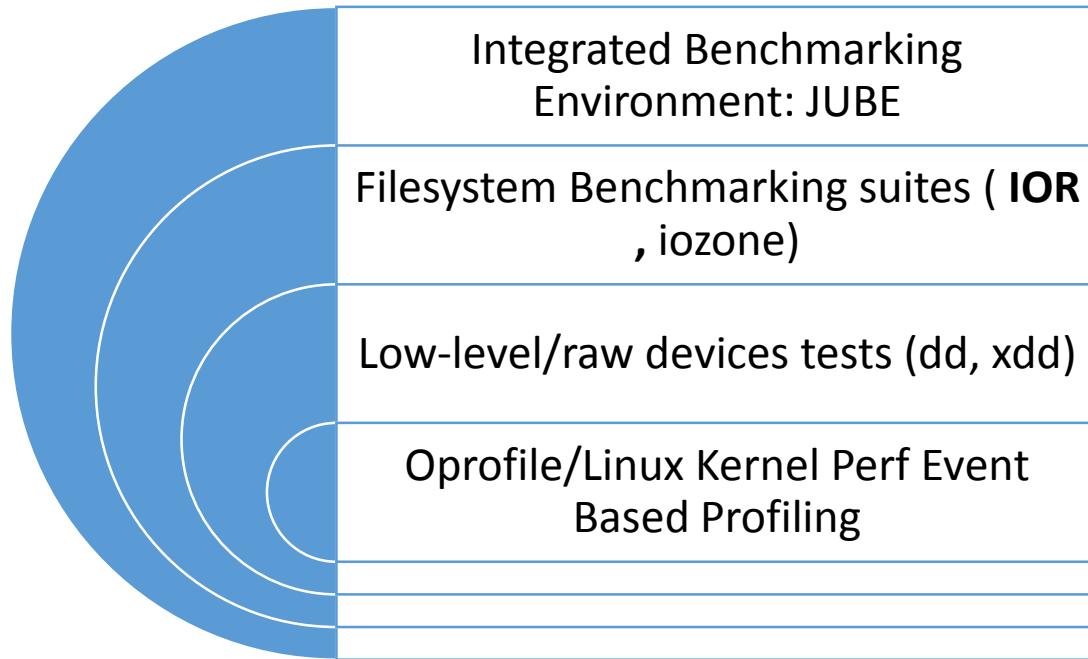

# Current Lustre work toward the trade-off

- Performance & efficiency : benchmarks, analysis, hardware tests
- Scalability: Tests on very large integrated systems
- Cap-ex: Commodity Lustre
- High-Availability: Efficient Software RAID
- Implementation Risks: Accumulating and recording know-how

# Performance Benchmarking

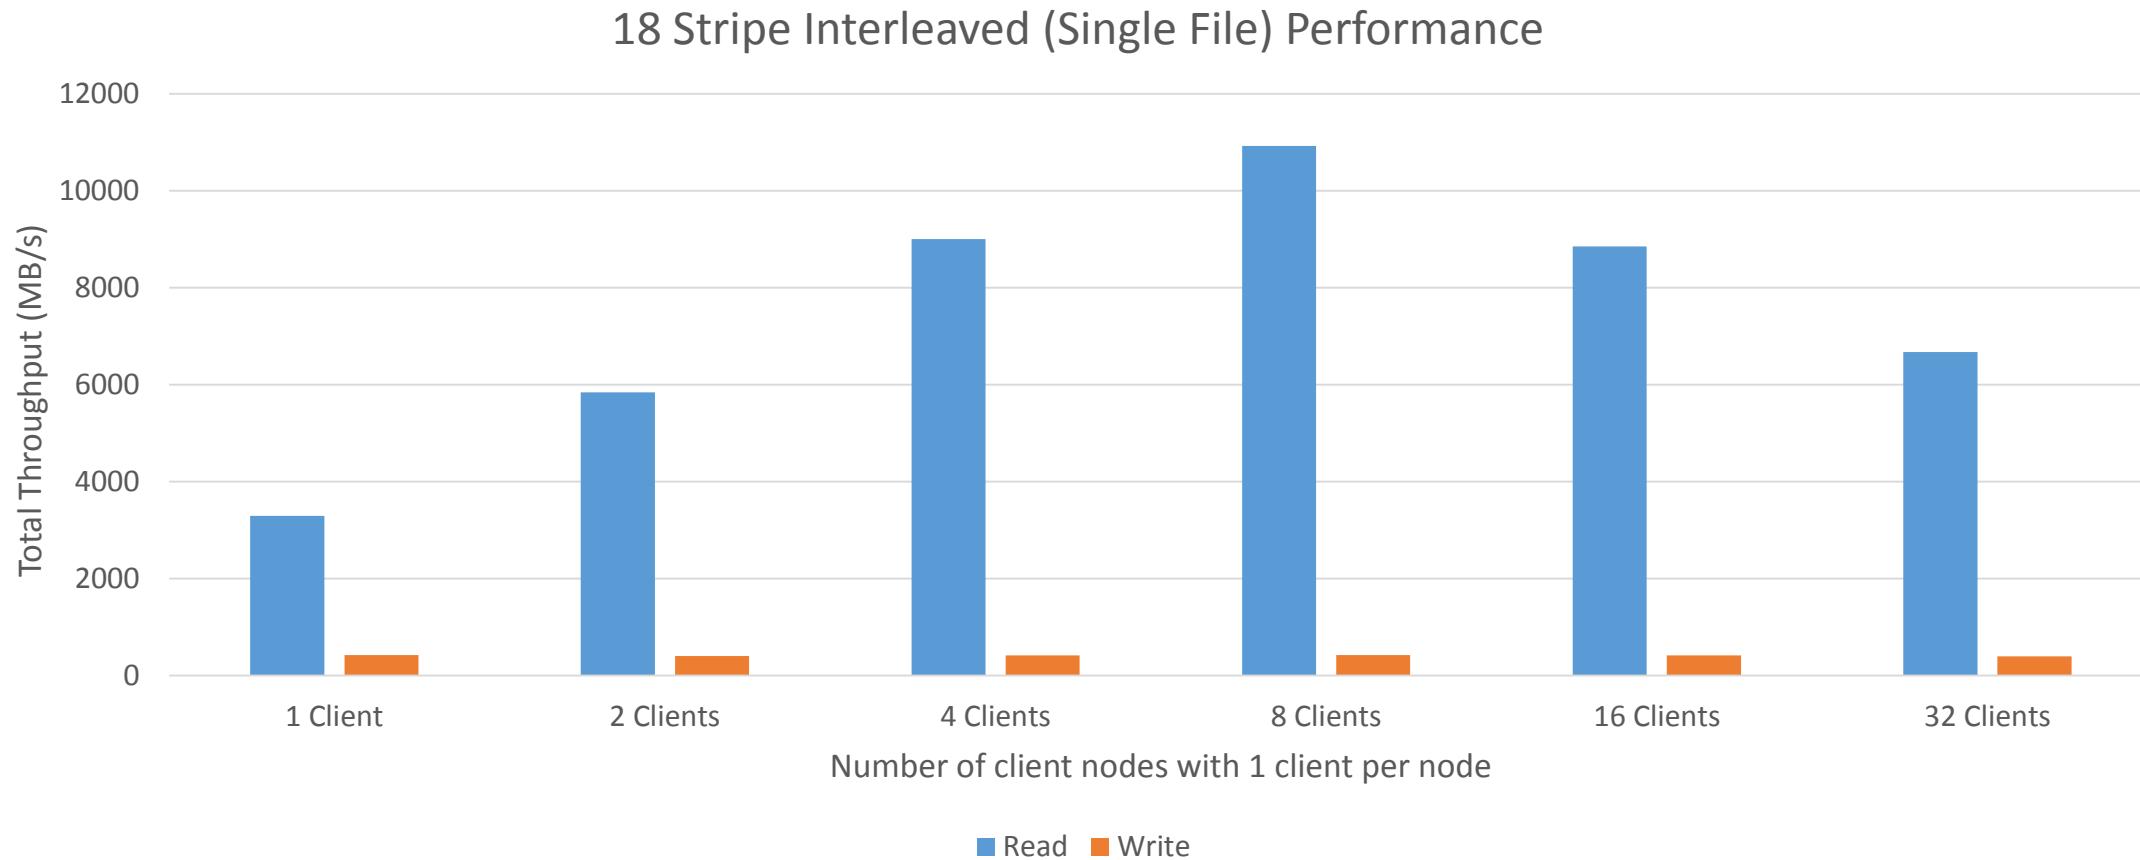

Aims: Measure Real World Performance, Identify Bottlenecks, Quantify Scaling

# Lustre Benchmarking Approach

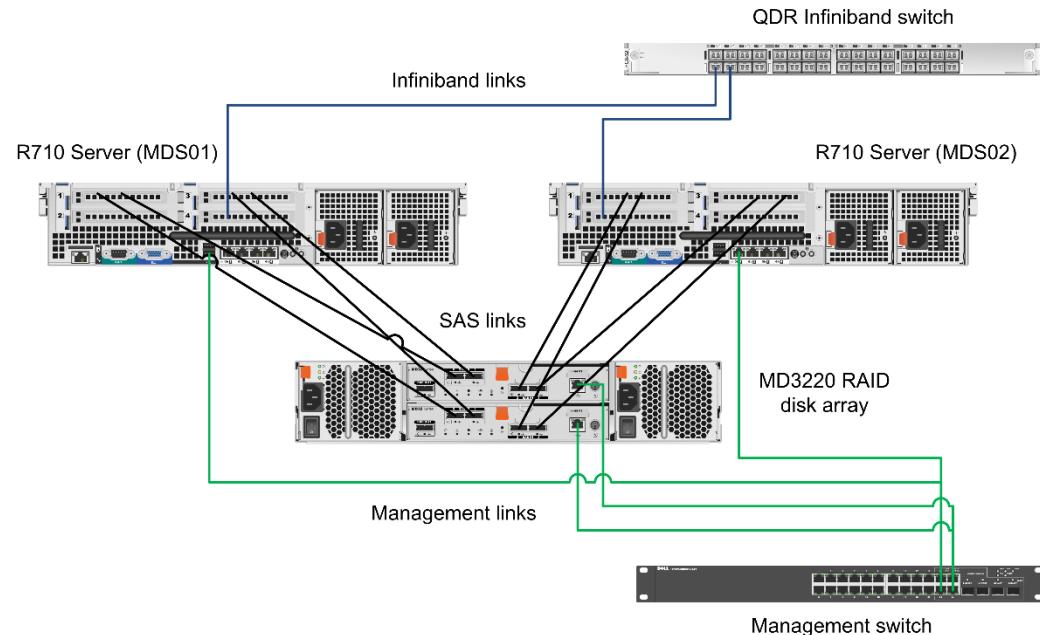

- Application tests: ASKAPSoft (in preparation)

# Lustre Development Hardware Platform at HPCS

Test Brick Gen 2

# Object Storage Servers: Dell R720

2 x quad 6Gb/s SAS HBA

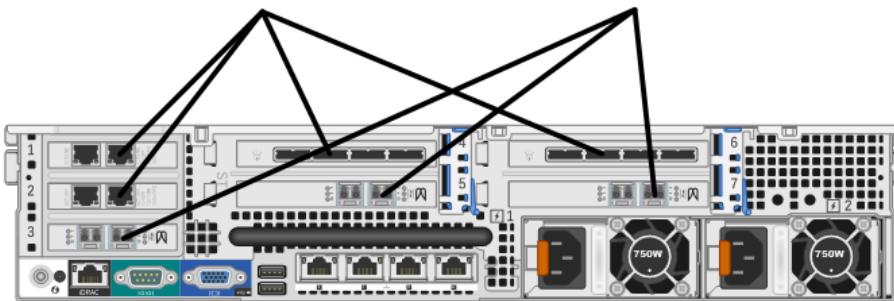

2 x dual 6Gb/s SAS HBA

Each port has 4 lanes 6Gb/s lanes

In total all for HBAs can deliver 25GBytes/s

3 x dual port FDR IB HCAs

In total 3 x dual port HCAs  
can deliver 24GBytes/s

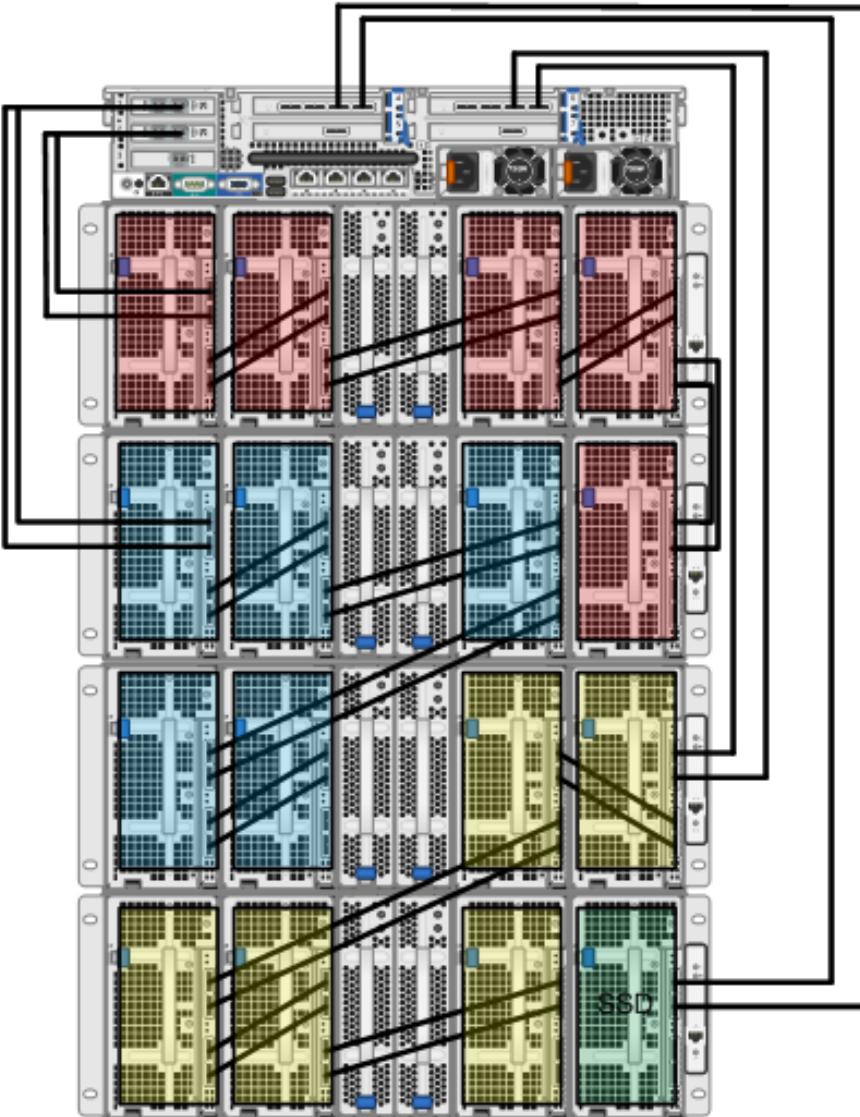

40 units theoretically give 1 Tbyte/s

## Object Storage Block

- 16 x C8000XD sleds
- Each Sled: 12 4TB NL-SAS 7.2k HDDs
- Total capacity: 768 TB
- Total throughput: 20 GB/s
  
- Theoretically 50 units to reach 1 Tbyte/s
- Theoretically ~130 units to reach 100 Pbyte of capacity

2.16GB/s per link

# Lustre Development at HCPS

## High Performance Lustre On Commodity Hardware

- Know-how in setting up and tuning Lustre systems for maximum performance
- Linux Kernel development (in collaboration with Calsoft Inc and Peter Braam)
  - High-Performance (*zero copy*) Software RAID6 for Lustre
- Know-how on maintenance and high-uptime for large Lustre implementations

# Future SDP Plans

- Demonstration of very high performance Lustre (> 40 GB/s) on commodity hardware
- Creation IOR scenarios that precisely mimic SDP UV buffer access patterns. Tests on large computer clusters in UK, Germany, Australia and South Africa
- Global Filesystem -> Accelerator IO tests (Cambridge has a 256 K20x cluster)
- Report on scalability limitations of global filesystems
- Investigation of object/key and hybrid global storage systems, compare to filesystems
- Impact of data formatting (e.g., HDF5) on global filesystem performance
