

Micro Pattern Gas Detector

Oliveri Eraldo (PH-DT-DD)

MPGD detectors already running at CERN....

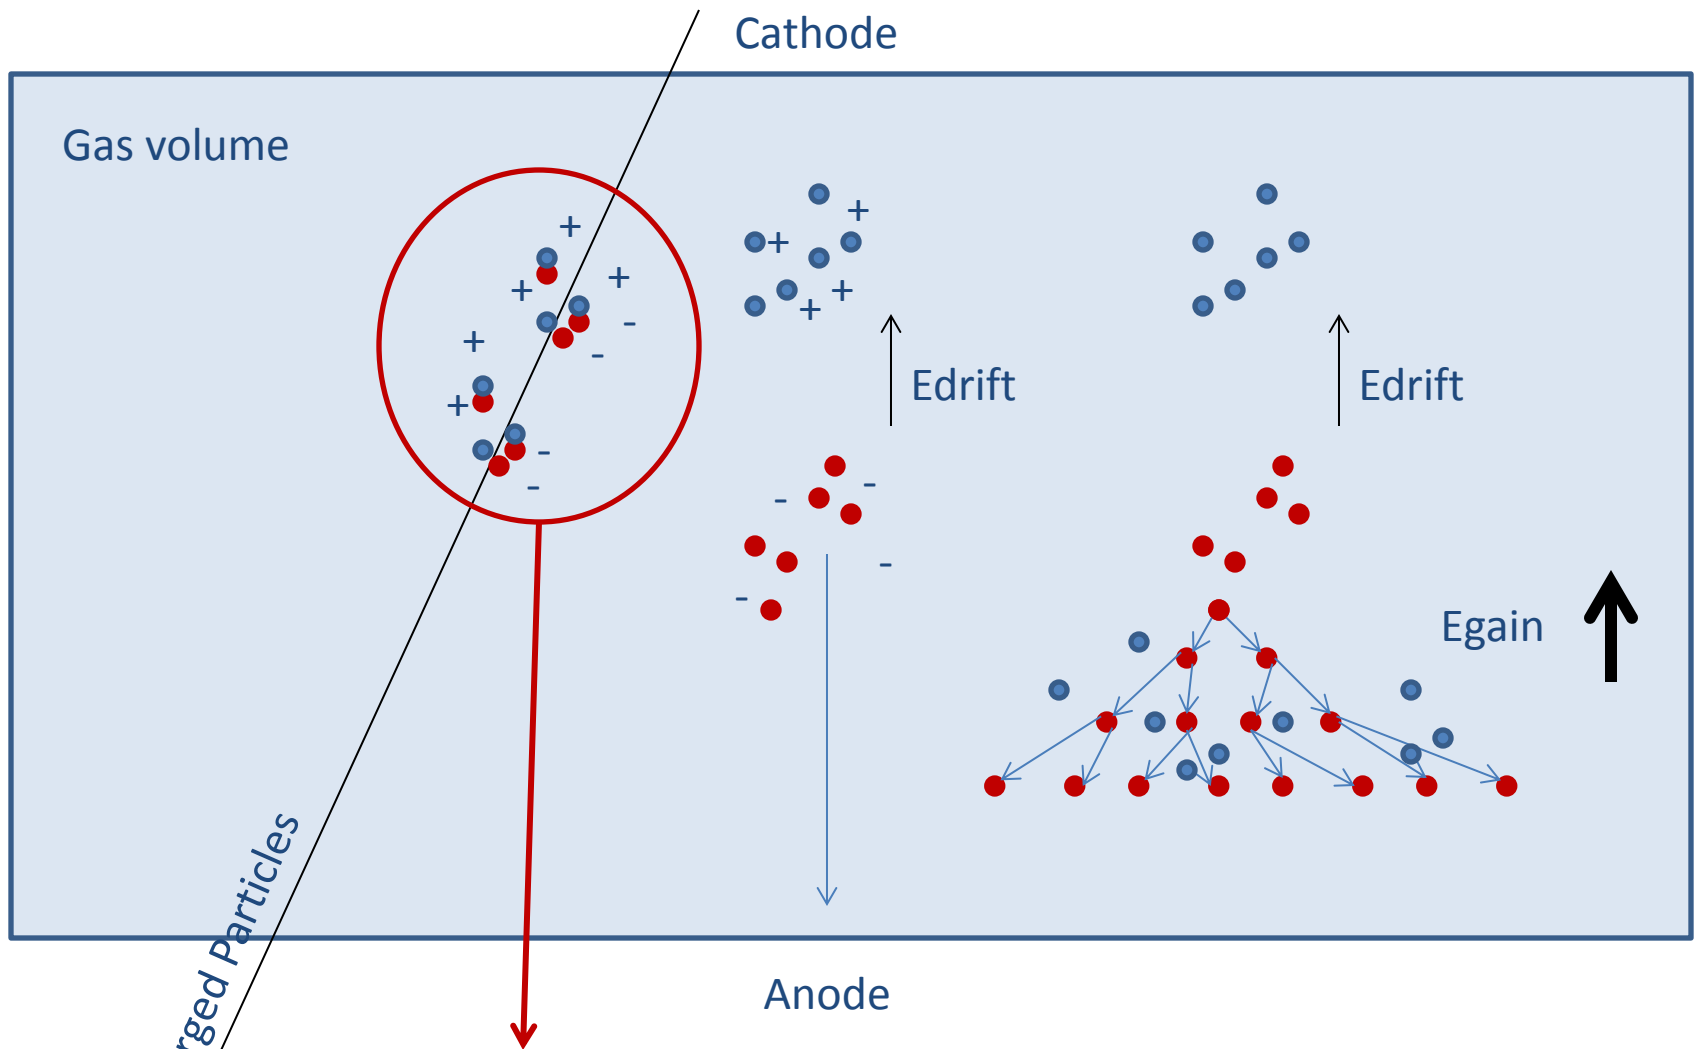

.... and possible upgrades

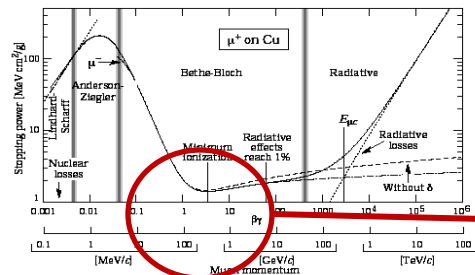

... but I will not talk directly about them

- Mostly focused on the detector...
- You will not find therefore a list of current, future solutions and fields of application... (actually they are too many and someone would be for sure unhappy if forgotten...)
- We will mostly discuss about problems to better understand the mechanisms and maybe trigger some new ideas...
- Because of this we will discuss also about maybe out-dated detectors... (all the critical point are fixed in the current MPGDs and therefore no reason to talk about them!?? ...)

Charged particles

You have to learn how to play with fields

MIP $\approx 2 \text{ MeV cm}^2/\text{g}$

Energy loss due to electromagnetic interaction

Multi Wire Proportional Chamber (G. Charpak, 1968): a pattern detector

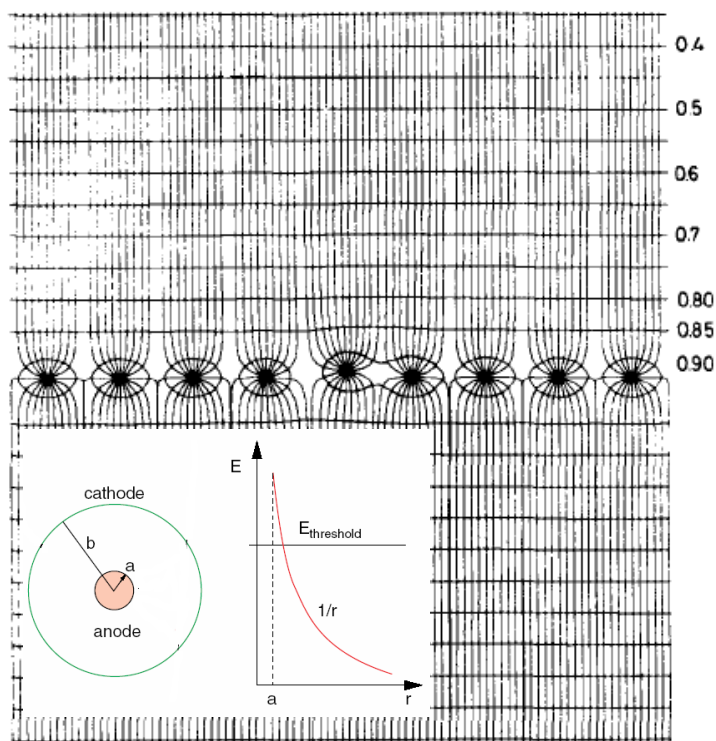

Fig. 56 Electric field equipotentials and field lines in a multiwire proportional chamber. The effect on the field of a small displacement of one wire is also shown³⁷⁾.

G. Charpak, D. Rahm, H. Steiner, Some developments in the operation of multiwire proportional chambers, Nuclear Instruments and Methods, Volume 80, Issue 1, 1970, 13-34

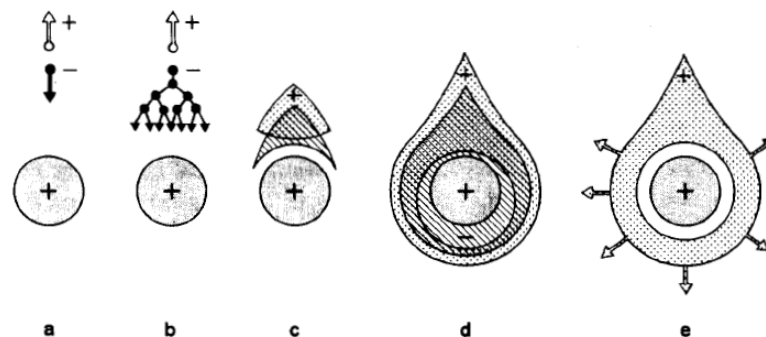

Fig. 49 Time development of an avalanche in a proportional counter³⁰⁾. A single primary electron proceeds towards the anode, in regions of increasingly high fields, experiencing ionizing collisions; due to the lateral diffusion, a drop-like avalanche, surrounding the wire, develops. Electrons are collected in a very short time (1 nsec or so) and a cloud of positive ions is left, slowly migrating towards the cathode.

F. Sauli, Principles of operation of multiwire proportional and drift chambers, CERN-77-09, [G. Charpak, Filet a particules, Découverte (février 1972)]

•Limited space resolution multi-track separation

mechanical instabilities due to electrostatic repulsion - less than 10cm length for 1mm spacing

•Fast gain drop at high fluxes

field-distorting space charge accumulation due to the long time taken by the ions produced in the avalanches to clear the region of multiplication

•Aging

permanent damage of the structures after long-term exposure to radiation due to the formation of solid deposits on electrodes.

The basic idea: move down in size & add cathodes very close to anodes to evacuate ions produced during the avalanche process

*Higher Spatial resolution and multi-track separation
(granularity)
Higher Rate (Faster Ions Evacuation)*

- Insulating material in between amplifying anode and cathode
- High electric field in most of the region in between the amplification stage electrodes
- Micro-Anode (wire style) structures

- Insulating material in between amplifying anode and cathode

It will affect almost everything... let's say stability issue

- High electric field in most of the region in between the amplification-stage-electrodes

Avalanche → Streamer → Spark

- Micro-Anode (wire style) structures

Permanent deterioration (Aging) & Lethal damages (Sparks)

Space resolution and multi-track separation

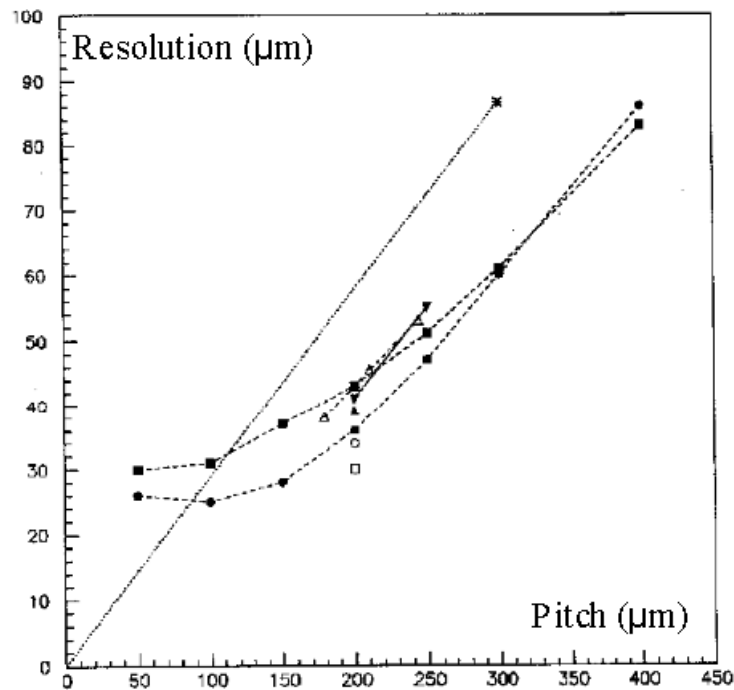

Fig. 17: Space resolution as a function of pitch.

Development of high rate MSGCs: Overview of results from RD-28, F. Sauli, CERN [S. Snow et al., Proc. Int. Workshop on Micro-Strip Gas Chambers (Lyon, 1995), 127.

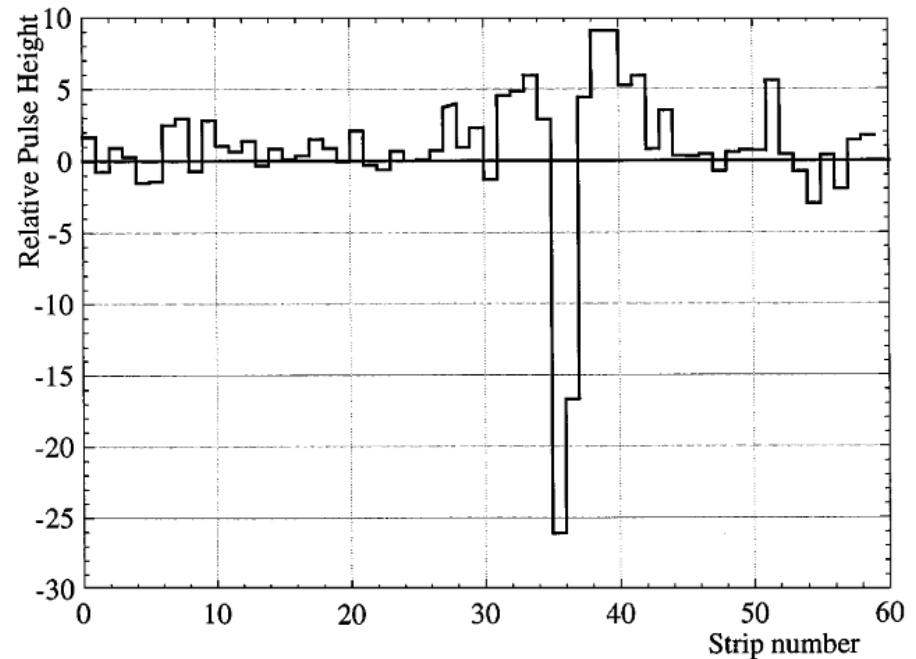

Figure 3 Typical pulse height profile recorded, for a localized avalanche, on adjacent anodes $200\ \mu\text{m}$ apart in a microstrip chamber. The positive overshoot is caused by a signal reinjection from the grouped cathode strips. The width of the distribution, about two strips fwhm ($400\ \mu\text{m}$), determines the multitrack resolution.

F. Sauli, A. Sharma, Micropattern Gaseous Detectors, Annu. Rev. Nucl. Part. Sci. 1999. 49:341–88

Insulating material in between amplifying anode and cathode

“... a substantial increase of resistivity with time after the application of voltage, accompanied by a decrease of gain (Figure 7) and a rate-dependent gain shift (Figure 8), has been observed....

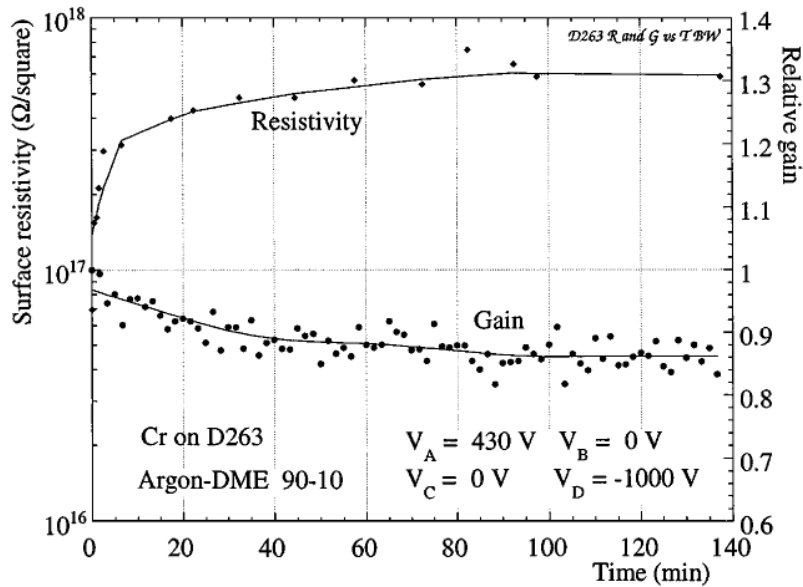

Figure 7 Initial gain variation of gain and resistivity as a function of time from the application of voltage for a plate made on insulating borosilicate glass substrate. V_A , V_B , V_C , and V_D are the anode, back-plane, cathode, and drift potentials, respectively.

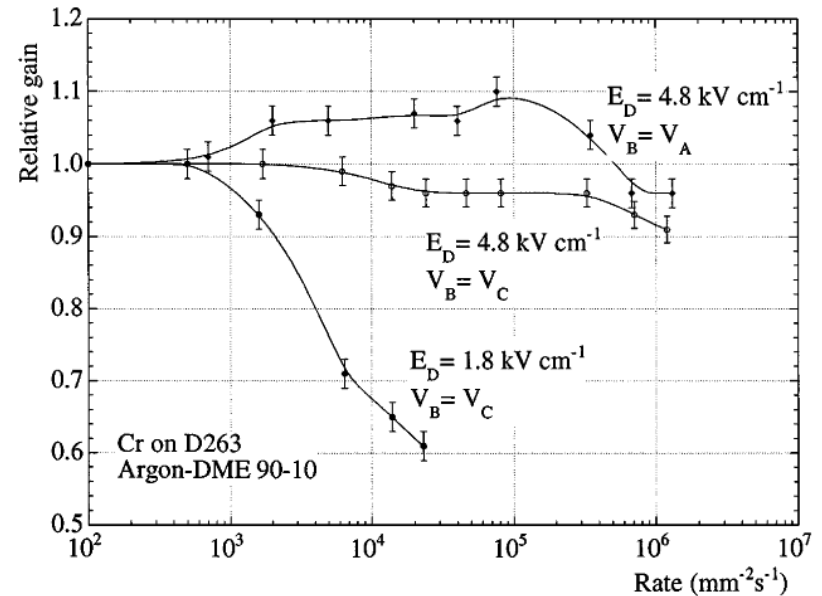

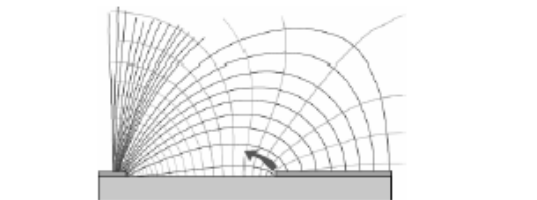

Figure 8 Relative gain as a function of irradiation rate, measured on a microstrip made on borosilicate glass. The performance depends strongly on the applied voltages. E_D is the drift field; V_B and V_C are the back-plane and cathode potentials.

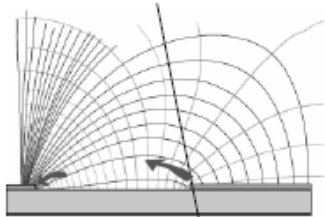

The effects are attributed to a dynamic modification of the electric field following the application of voltage and to substrate polarization, internal rearrangements of the charge carriers, and surface charge accumulation...” *F. Sauli, A. Sharma, Micropattern Gaseous Detectors, Annu. Rev. Nucl. Part. Sci. 1999. 49:341–88*

High electric field in most of the region in between the amplification-stage-electrodes (from avalanche to discharge)

HIGH RATE BEHAVIOR AND DISCHARGE LIMITS IN MICRO-PATTERN DETECTORS

A. Bressan et al. CERN-EP/98-139, 18 September 1998

Triggered by the invention, ten years ago, of the micro-strip gas chamber (MSGC) [1], during the last decade a new generation of fast, performing gas detectors has emerged, relying for manufacturing on more or less sophisticated photo-lithographic patterning technologies. A non-exhaustive list of such innovative devices includes the micro-gap [2], micro-dot [3], “compteur à trous” (CAT) [4], small gap [5], micromegas [6], gas electron multiplier (GEM) [7], micro-CAT [8], micro-groove and WELL detectors [9, 10]. For a recent review see for example [11, 12]. All these devices, here collectively named micro-pattern detectors, share a common characteristics setting them aside in behavior from multiwire counters: a high electric field extends over a large fraction or all of the gap between anodes and cathodes, generally very narrow (few tens to few hundred μm), and in most cases high field singularities also exist close to the cathode surface.

It should be recalled that in multiwire proportional chambers and derivatives, having a high electric field around the thin wires but well below the critical values for multiplication in most of the remaining volume, a transition from proportional to streamer regime is also observed at high voltages, but in most cases the streamer propagation stops in the decreasing field well before reaching the cathode. The limited streamer regime has been widely exploited for obtaining conveniently large signals in wire counters [30] and has as sole shortcoming a modest rate capability.

Micro-Anode (wire style) structures & Aging

Micro-Anodes:

Smaller amplification volume, higher energy density in the avalanche plasma.
Large effects on the field (deposit) as for wires.

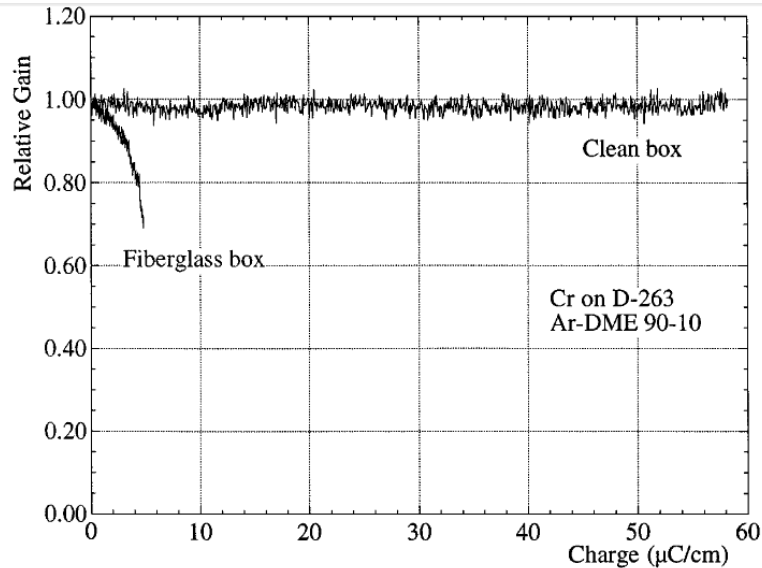

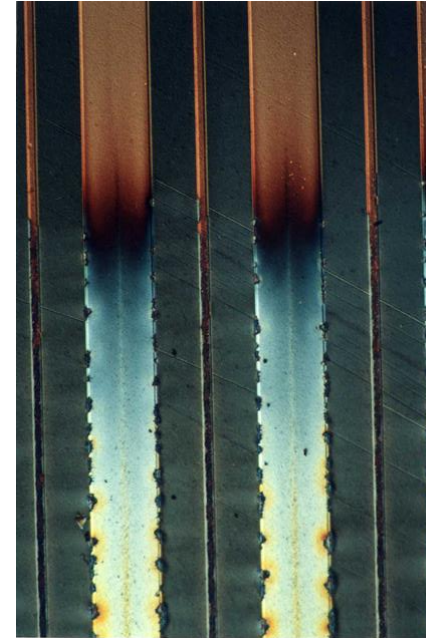

Figure 21 Comparison of aging rate under irradiation for identical plates, mounted either in a conventional fiberglass assembly or in a clean container.

Bouclier R, et al. In Proc. MSGC Workshop,
Legnaro, p. 48 (1994)

medium- and long-term stability determined by physical parameters used to manufacture and operate the detectors as : substrate material, metal of the strips, type and purity of the gas mixture

DEVELOPMENT OF HIGH RATE MSGCS: OVERVIEW OF RESULTS FROM RD-28

Fabio Sauli, CERN, CH-1211 Geneva, Switzerland

Some stability problems have however been met:

- gain modifications due to substrate polarization and charging up
- permanent deterioration (ageing) during sustained irradiation

...

the situation is complicated by the interdependence of the various parameters.

...

These effects are attributed to

- modification of the electric field by substrate polarization following the application of the potentials
- charging up of the insulator by electrons and ions produced in the avalanches
- ions migration within the substrate.

...

Use of a substrate with lower resistivity and electronic conductivity eliminates the polarization and surface charging processes up to very high rates; it results also in more stable operation and reduced ageing rates.

- metal: gold (0.6-0.8 μm)
- undercoating: Pestov or S8900 glass (0.5-1 μm)
- substrate: Desag glass (300 μm)

Substrate: Aging

All other conditions being equal, use of low-resistivity substrates permits higher levels of exposure without loss of gain (40, 49, 132), possibly by reducing the effect of thin deposits on the field. The choice of metal for the strips also appears to play an important role (71), gold being the best (Figure 22) (133).

High rate behavior and discharge limits in micro-pattern detectors

A. Bressan^a, M. Hoch^a, P. Pagano^a, L. Ropelewski^a, F. Sauli^{a,*}, S. Biagi^b, A. Buzulutskov^c,
M. Gruwé^d, G. De Lentdecker^e, D. Moermann^f, A. Sharma^g

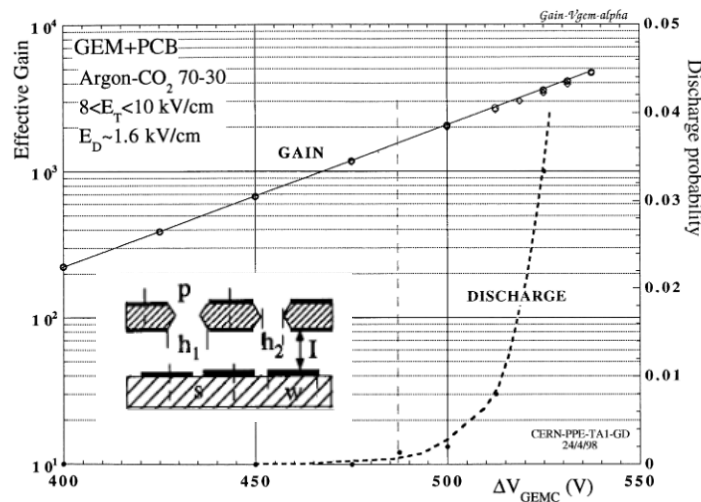

Fig. 9. Effective gain and discharge probability on the internal α source obtained with the GEM detector with an argon- CO_2 gas filling.

GEM + PCB: GEM: 5 μm Cu on 50 μm kapton
 $p = 140 \mu\text{m}$, $h_1 = 80 \mu\text{m}$, $h_2 = 55 \mu\text{m}$
 PCB: 5 μm Cu on 50 μm kapton
 $s = 100 \mu\text{m}$, $w = 150 \mu\text{m}$
 Induction gap $I = 1 \text{ mm}$. Active area: $10 \times 10 \text{ cm}^2$

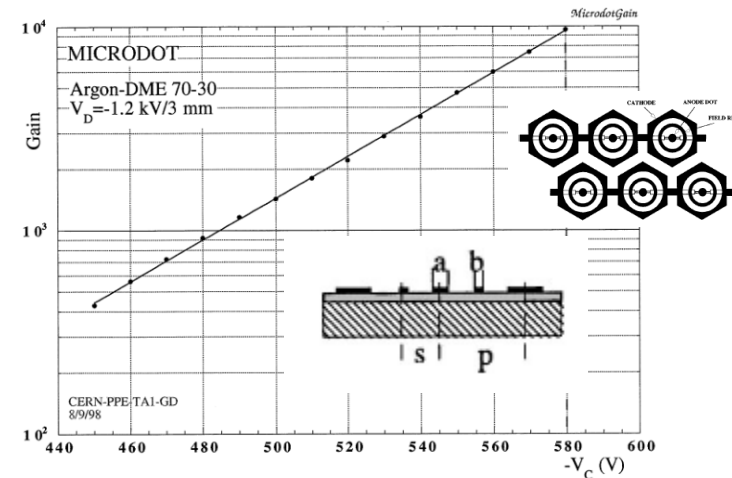

Fig. 15. Gain as a function of voltage in the micro-dot detector. No effect of the internal α source has been observed up to a gain of 10^4 .

Micro-dot: Anode diameter $a = 24 \mu\text{m}$ Guard ring
 $b = 5 \mu\text{m}$ $s = 55 \mu\text{m}$
 Pitch $p = 100 \mu\text{m}$
 Active area: $6 \times 0.6 \text{ cm}^2$

Remarkably, and in opposition to all other devices tested, introduction of the α emitter did not result in any sign of discharge, up to gains of 10^4 ; at this point, and short of reaching 2×10^4 , a fatal breakdown resulted in the destruction of the detector.⁶

This suggests that the low field at the cathode surface and the intermediate field ring act as an effective stop against the formation and propagation of streamers;

Uniform Field Amplification & MPGD

“...The successful development of multiwire and microstrip structures has somewhat sidestepped the research on gas detectors that exploit the multiplication in uniform fields. Parallel-plate multipliers not only are mechanically sturdier but also have better energy resolution and higher rate capability. ”

PACS.29.40.Cs – Gas-filled counters: ionization chambers, proportionnal and avalanche counters
PACS.29.40.Gx – Tracking and position-sensitive detectors

Abstract. — A simple geometry of real pixel gas detectors has been evaluated that overcomes the limitations of a microstrips, namely aging, gain drift and flux limitation due to the charging. A good resolution has been obtained while preserving a large active size gain and counting rate capabilities.

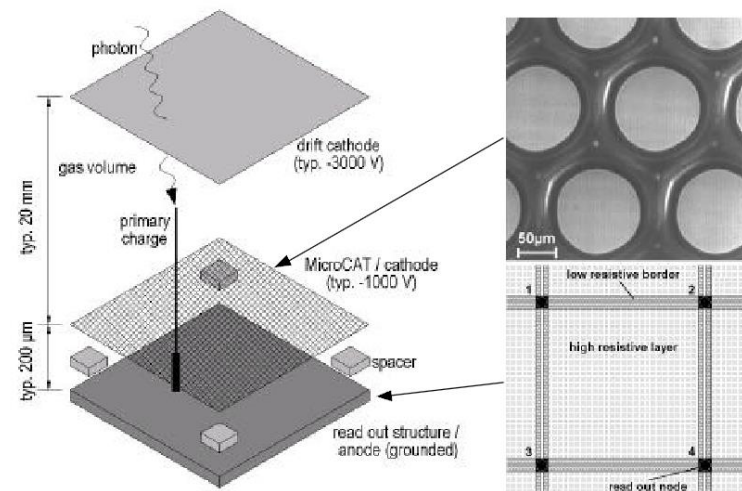

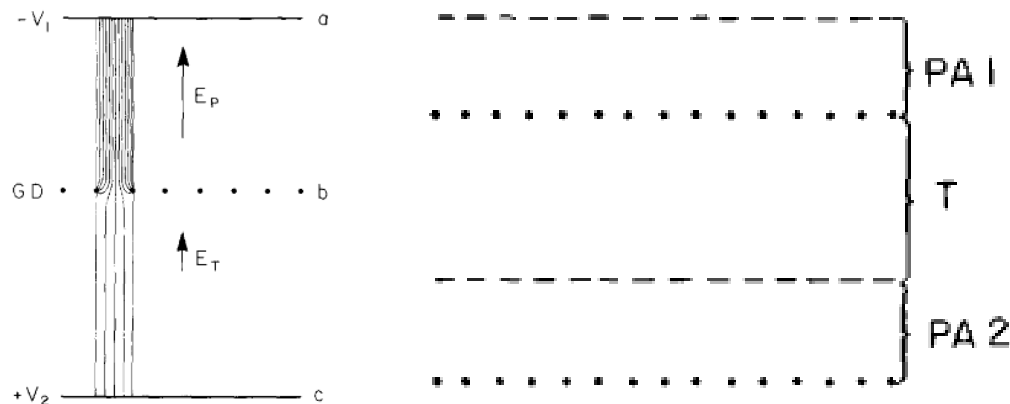

Fig. 4: Exposed view of the prototype detector plus details of the gas gain structure (MicroCAT) and the resistive position encoding structure (one single interpolation cell). The full active area of 28 x 28 mm² is composed of 7 x 7 interpolation cells, each one 4 x 4 mm² in size.

Cellular resistive readout using a resistive anode foil that is padded with conducting lines and forms a regular matrix of nodes, each connected to a charge-sensitive amplifier.

Resistive layer (to improve spatial resolution)

Multistep Avalanche Chamber (Charpak G, Sauli F. Phys. Lett. B78:523 (1978))

Made with a succession of metal meshes, the detector multiplied ionization electrons injected from a drift region into a high field. A fraction of the avalanche was then transferred through a lower field region into a second element of multiplication, a parallel plate or a wire chamber. Despite the loss of charge in the transfer from high to moderate fields, effective preamplification factors of several hundred were possible. Followed by a standard MWPC, the device permitted the high gains necessary to detect single photoelectrons.

PAT
[PreAmplification and Transfer]

**To obtain larger gains with
parallel-plate structures**

“The multistep chamber was mechanically complex to implement and had only limited success, but demonstrated the great potential of subdividing the gain among several cascaded elements separated by low-field gaps”

GEM (gas electron multiplier) introduced by Sauli in 1997, consists of a thin, metal-clad polymer foil chemically perforated by a high density of holes, typically 100/mm²

GEM: A new concept for electron amplification in gas detectors
F. Sauli, Nucl. Instr. and Meth. A386(1997)531

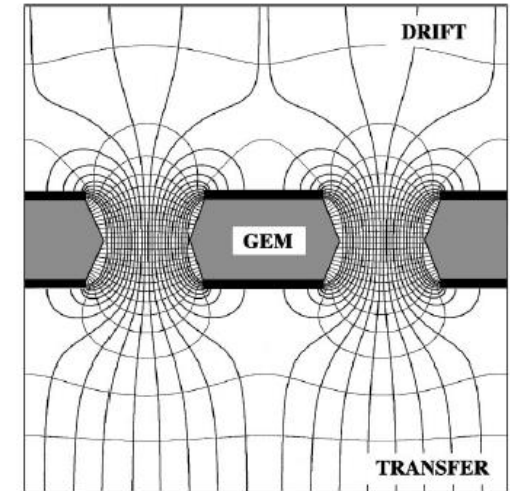

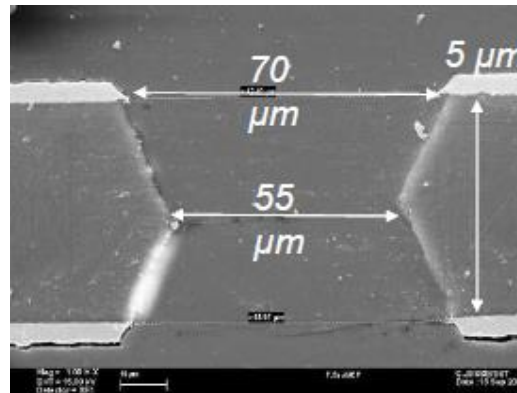

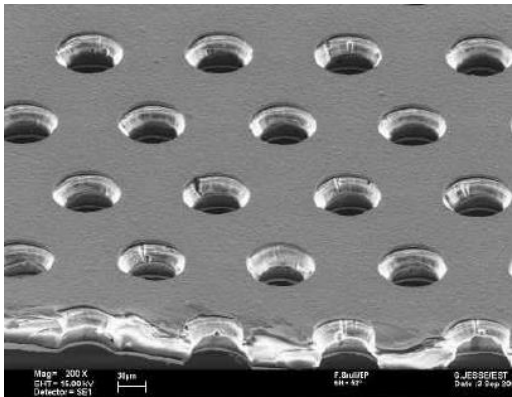

Figure 34 Electric field and equipotentials lines in the gas electron multiplier.

UNIQUE FEATURE

PREAMPLIFICATION AND TRANSFER OF CHARGE PRESERVING THE IONIZATION PATTERN

Sharing of the gain between two or more cascaded amplifiers, each operated at a voltage well below the discharge limit, appears to be a good solution to the problems common to all single-stage micro pattern detectors.

Thick GEM

(R. Chechik, A. Breskin and C. Shalem, Thick GEM-like multipliers—a simple solution for large area UV-RICH detectors, to be published in NIMA - Similar approach to Peskov's “optimized GEM”)

THGEM Peculiarity

Geometrical parameters scale respect with standard GEM

while

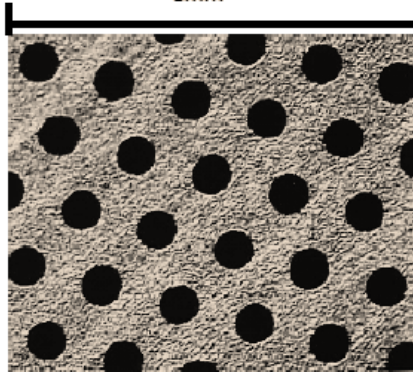

microscopic behavior of the electrons does not (in particular diffusion in the gas)

therefore

More effective electron collection and transport between cascaded elements
(hole diameter is larger than the electron's diffusion range when approaching the hole)

Standard GEM

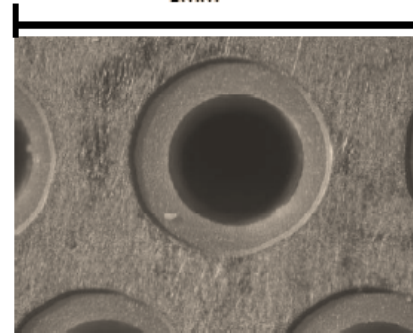

1mm

- Microlithography + etching
- High Spatial resolution (tens of microns); $V_{GEM} \sim 400V$
- $>10^3$ gain in single GEM
- 10^6 gain in cascaded GEMs
- Fast (ns)
- Low pressure - gain ~ 30

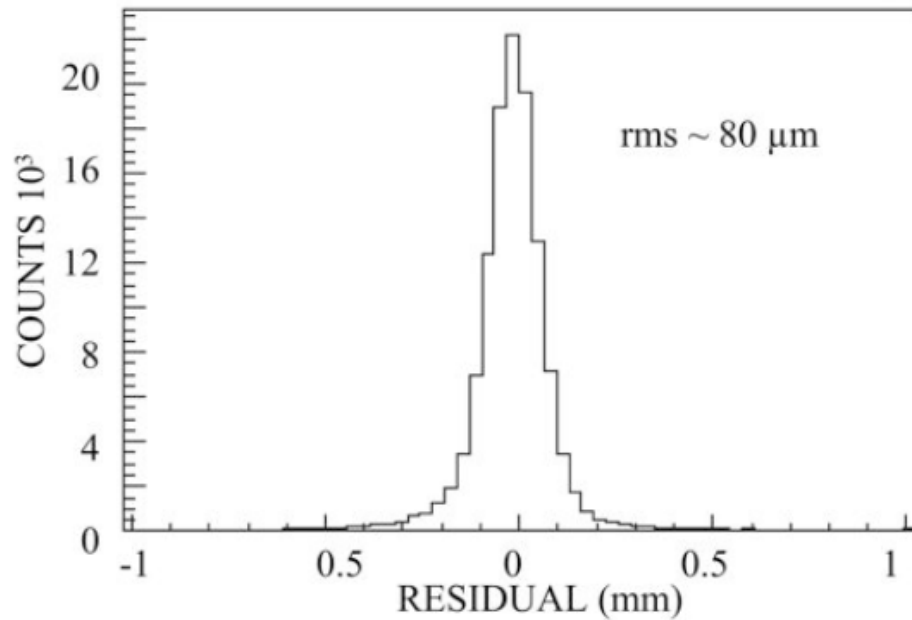

TGEM*

1mm

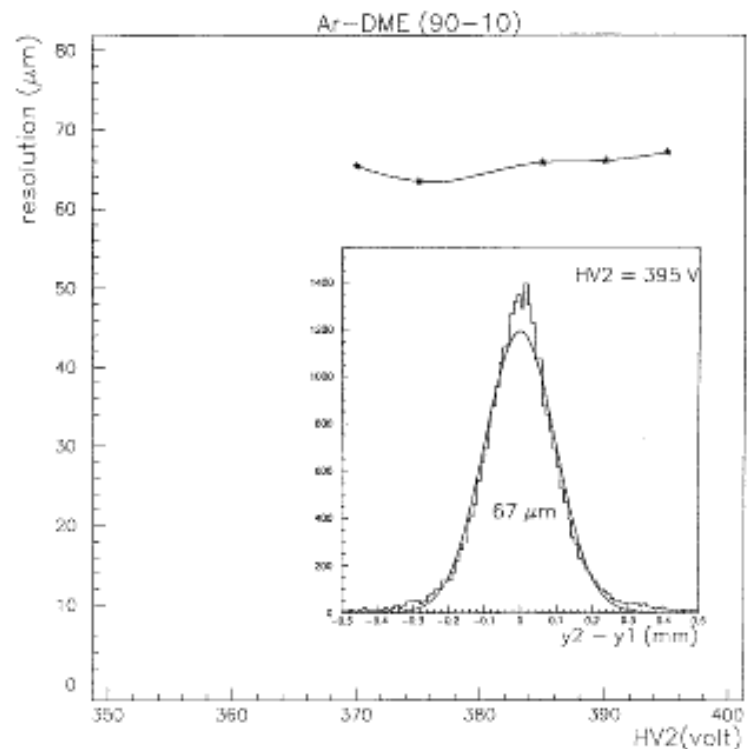

- PCB tech - etching + drilling
- Simple and robust
- $V_{TGEM} \sim 2KV$ (at atmospheric pressure)
- 10^5 gain in single- & 10^7 double-TGEM
- Sub-mm to mm special resolution
- Fast (ns)
- Low pressure (<1 Torr) gain 10^4

Space Resolution

New MPGDs & Discharges

Discharges in new MPGDs

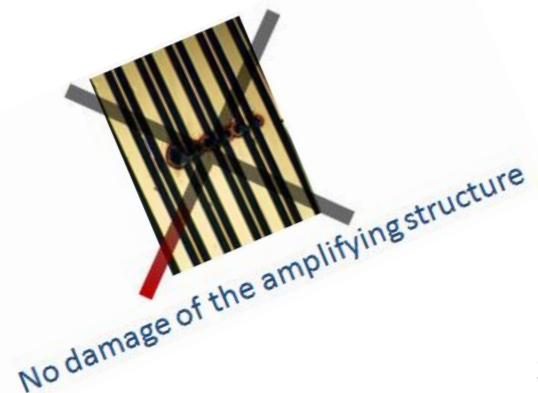

**MPGD faster because of smaller gaps between anode and cathode but:
streamer -> fast discharges**

- **Spontaneous breakdown, in absence of radiation, above a critical voltage**
- **Rate-induced breakdown (presence of long-lived excited states produced in the gas or, according to recent evidence, more likely on the electrode surface)**
- **Heavily ionizing tracks**

High rate behavior and discharge limits in micro-pattern detectors. A. Bressan et al, Nuclear Instruments and Methods in Physics Research A 424 (1999) 321

Let's have a look to mesh and hole based MPGD, micromegas and GEM. Two different approach followed against discharges:

1. *Single Stage Detectors → Resistive Material*
2. *Multi stage detectors → Gain sharing*

Micromegas

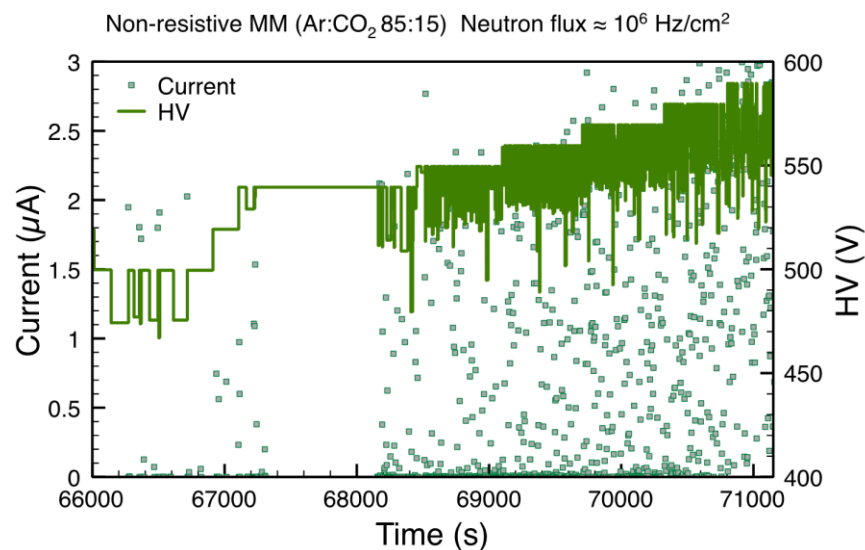

Something good:

Amplifying structure not destroyed by discharges
(studier structure)

Something to fix:

Inacceptable high spark rate at LHC operating
conditions with standard micromegas

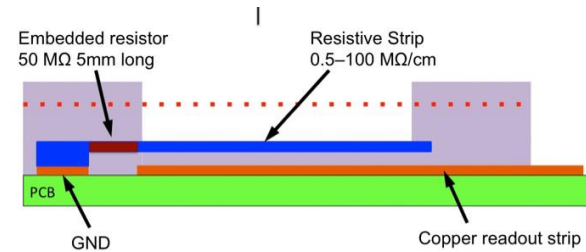

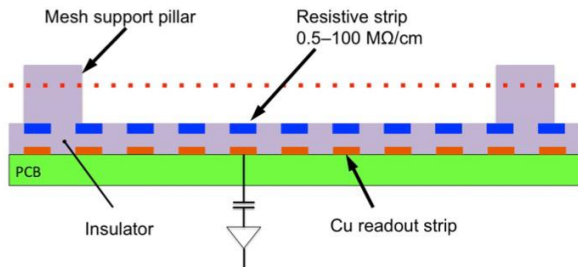

High Voltage and
Current in the mesh
under neutron
irradiation

Less sensitive \neq Insensitive

Usual control of the quality of the gas system is strongly suggested as the selection and test of all the material in contact with the gas volume and all the precaution used to be protected against aging (ref to single wire experience)

Aging (non classical)

LHCb

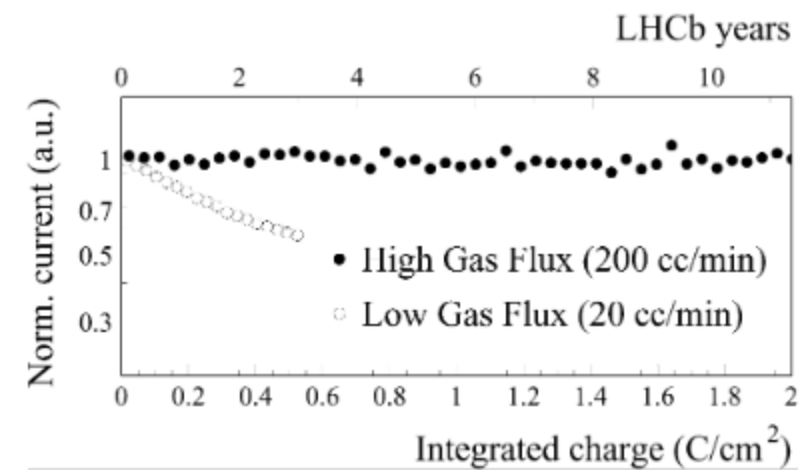

Fig. 14. Comparison between the aging measured on a small prototype with low gas flow ($\sim 20 \text{ cm}^3/\text{min}$) and high gas flow ($\sim 200 \text{ cm}^3/\text{min}$).

Ar/CO₂/CF₄
(45/15/40)

We have demonstrated that the etching observed during this test is clearly correlated with bad gas flow rate conditions. No aging occur if the gas flow is properly set.

1

- ◆ Strongest ageing at moderate intensity
 - Not much ageing at the highest intensity
 - => not proportional to accumulated charge
 - Highest ageing at ~ 0.2 mC/cm

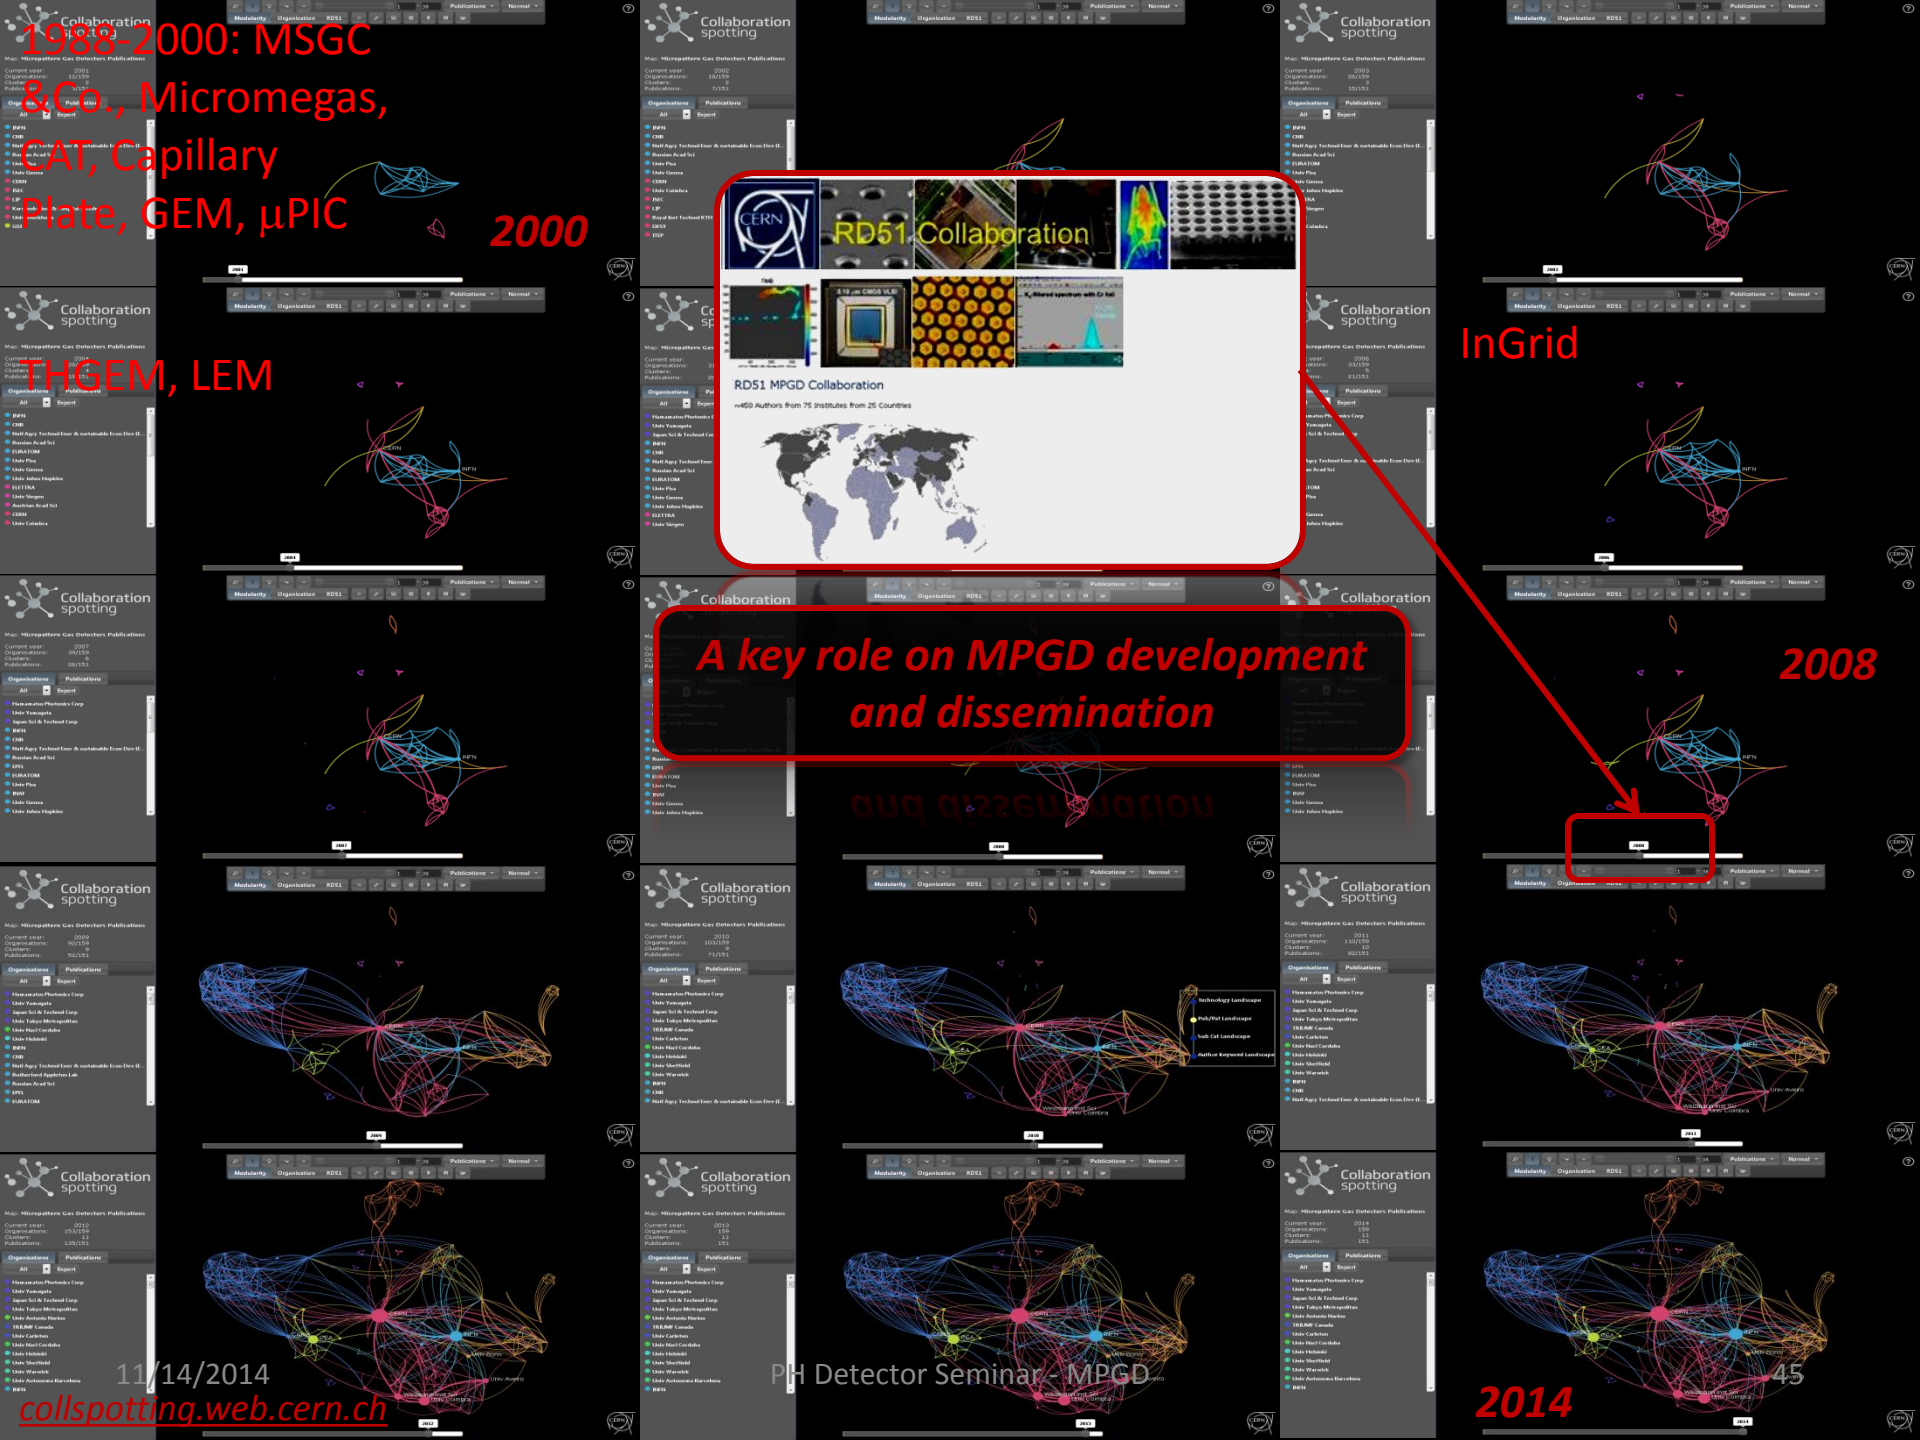

- ◆ Deposit on wire surface visible

PH Detector Seminar - MPGD

Conclusion

- A deep understanding of the detector physics allows the addressing of some gaseous detector and specifically MPGD issues. Wide and high level expertise developed in many years by many groups.
- Many possibility/structures to fit with the applications. As usual R&D needed to face the specific requirements/environments
- Among the others, uniform field MPGDs (micromesh and hole-type) represent nowadays a robust and mature-enough solution for many challenging applications... but they are not necessarily the only ones (again, case by case...)
- Micro Pattern fit with Large Area (not discussed but extremely important)..
- Wide spectrum of use, not only HEP ... not treated in this talk ... cryogenics, converter and mpgd (photons, neutron,..), extreme granularity using mpgd and integrated silicon FE...
- Large collaborative community behind these technologies (sharing common tasks and tools for boosting future perspectives – simulation, electronics, facilities).

We conclude as we started... with MWPC

It was the merit of Charpak and collaborators to recognize that the positive induced signals in all electrodes surrounding the anode interested by an avalanche largely compensate the negative signals produced by capacitive coupling; these authors operated in 1967-68 the first effective multiwire proportional chambers¹⁾, which comprised a set of anode wires closely spaced, all at the same potential, each wire acting as an independent counter.

High level of understanding is mandatory and sometime the common sense fails

F. Sauli, Principles of operation of multiwire proportional and drift chambers, CERN-77-09, 3 May 1977

Thanks (I'll upload a list of useful reference in the indico page..)

TPC @ LHC: ALICE TPC UPGRADE

The Gating Grid in MWPC

- An alternating voltage is applied to the GG 100 μ s after the collision (GG closed)
- It takes 180 μ s for the ions to reach the GG
- In this case IBF $< 10^{-4}$, but event rate limited to 3 kHz
- GG open results in IBF $\sim 5-8\%$ at gain 8000

4.10.2013

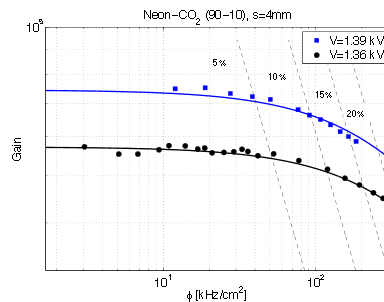

PH Detector Seminar - The ALICE TPC Upgrade

In addition, space-charge in the amplification region

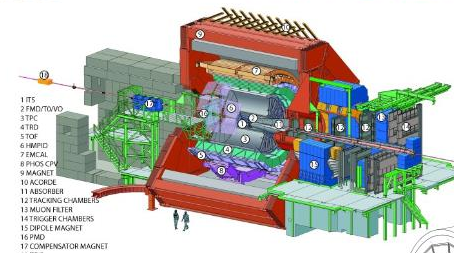

- Maximum particle rate of 40-100 kHz/cm² \rightarrow sizeable gain drop \rightarrow deterioration of dE/dx

- Replace MWPCs with GEMs
 - intrinsic ion blocking
 - high rate capability
 - allows for a factor 3 lower gain
 - new FEE needed!
- Keep Field Cage and everything else

S1 & S2 with LHM

Noble (liquid) Dreams

Amos Breskin
Weizmann Institute of Science

A dual-sided single-phase TPC DM detector with top, bottom and side THGEM-LHMs.
The prompt S1 scintillation signals are detected with all LHMs. The S2 signals are recorded with bottom and top LHMs.

Highlights:

- Higher S1 signals → lower expected detection threshold
- Shorter drift lengths → lower HV applied & lower e^- losses

It was believed that because of the capacitive coupling, the wires next to the amplifying wires would receive a sizeable part of the signal, and for this reason many attempts were made to have each sensitive wire separated by a shielding wire. However, this was costing a factor of two in the spatial resolution, and was limiting the lower distance between wires since a high voltage had to be applied between them.

In fact, if it is true that when you send a negative pulse, with an external generator, on one wire, you receive a sizeable negative pulse on the neighbouring wire, then the situation is different when you detect a particle by proportional amplification on a wire. You have indeed a negative pulse on this wire, but positive pulses on the neighbouring ones. This effect is due to the mechanism generating these pulses, namely the motion of the positive ions in the strong fields around the wires. This effect is responsible for the perfect localization of the pulses on the sensitive wires, irrespective of the distance between the wires. It is sufficient to have amplifiers that are sensitive only to the good polarity, to avoid the spurious effect of capacitive coupling between wires.
