

The Cygnus Region of the Galaxy: A VERITAS Perspective

Amanda Weinstein
Iowa State University

SuGAR 2015
Geneva

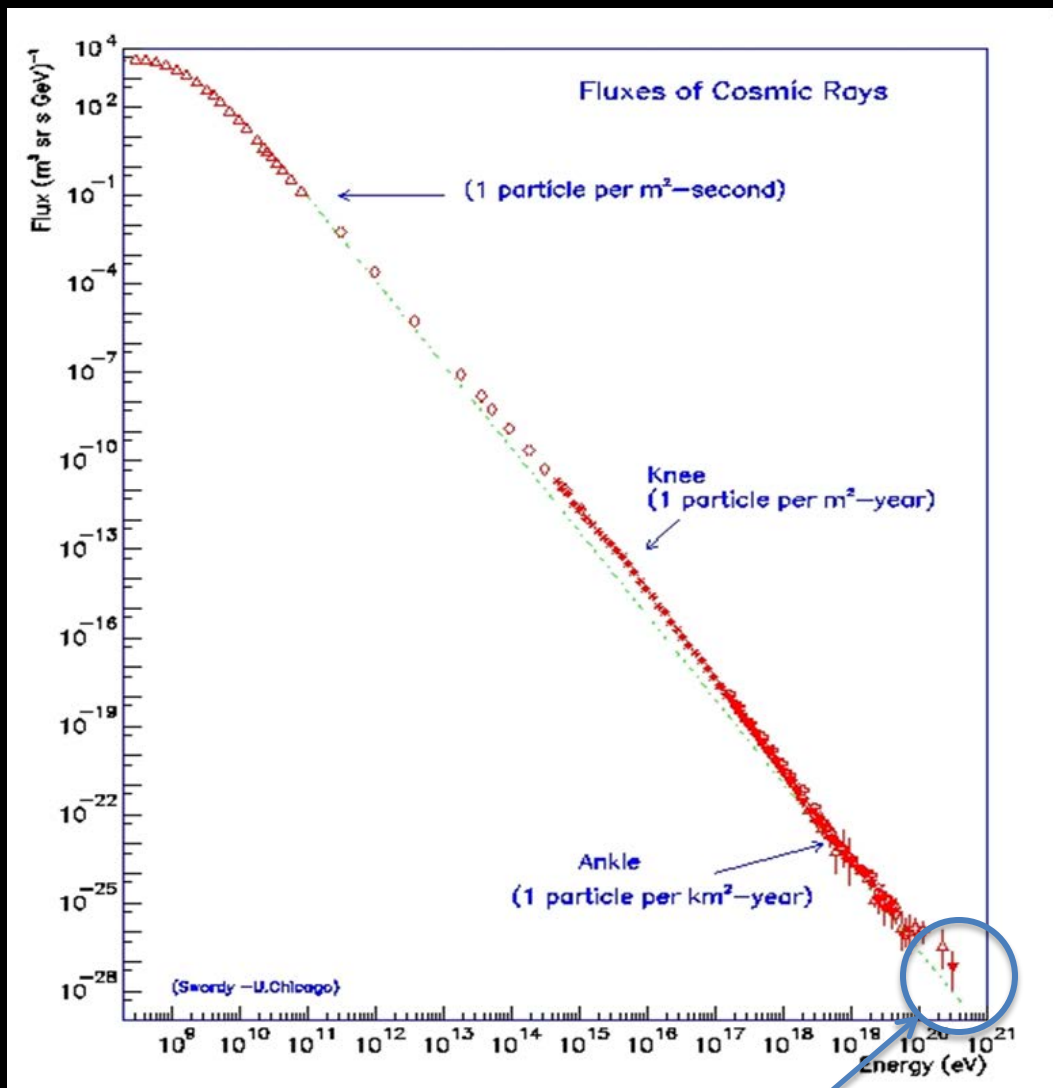

Hunting Cosmic Ray Accelerators

- Tracing particle populations with photons
- Information about acceleration mechanisms

Charged particle anisotropies

Tycho: hunting the cutoff (maximum proton energy)

- Problem: most energetic particles escape first (~30 yrs)
 - Hunting baby SNRs is hard!
- Cosmic ray escape signatures from accelerators? (individual, aggregate)

VERITAS Cygnus Region Survey: Motivations

- Source-agnostic look at a potentially source-rich region
 - High density of material
 - EGRET catalog sources, SNR/PWNe, &c.
 - Cygnus superbubble

High Energy Picture

Abdo et al. 2009

Specifications:

- Energy range: 100 GeV to > 30 TeV
- Energy resolution $\sim 15\%$ at 1 TeV
- Angular resolution (68% containment): 0.1° at 1 TeV, 0.14° at 200 GeV
- Source location accuracy: <50 arcseconds

Instrument design:

- Four 12-m telescopes
- 499-pixel cameras (3.5° FoV)
- FLWO, Mt. Hopkins, Az (1268 m)

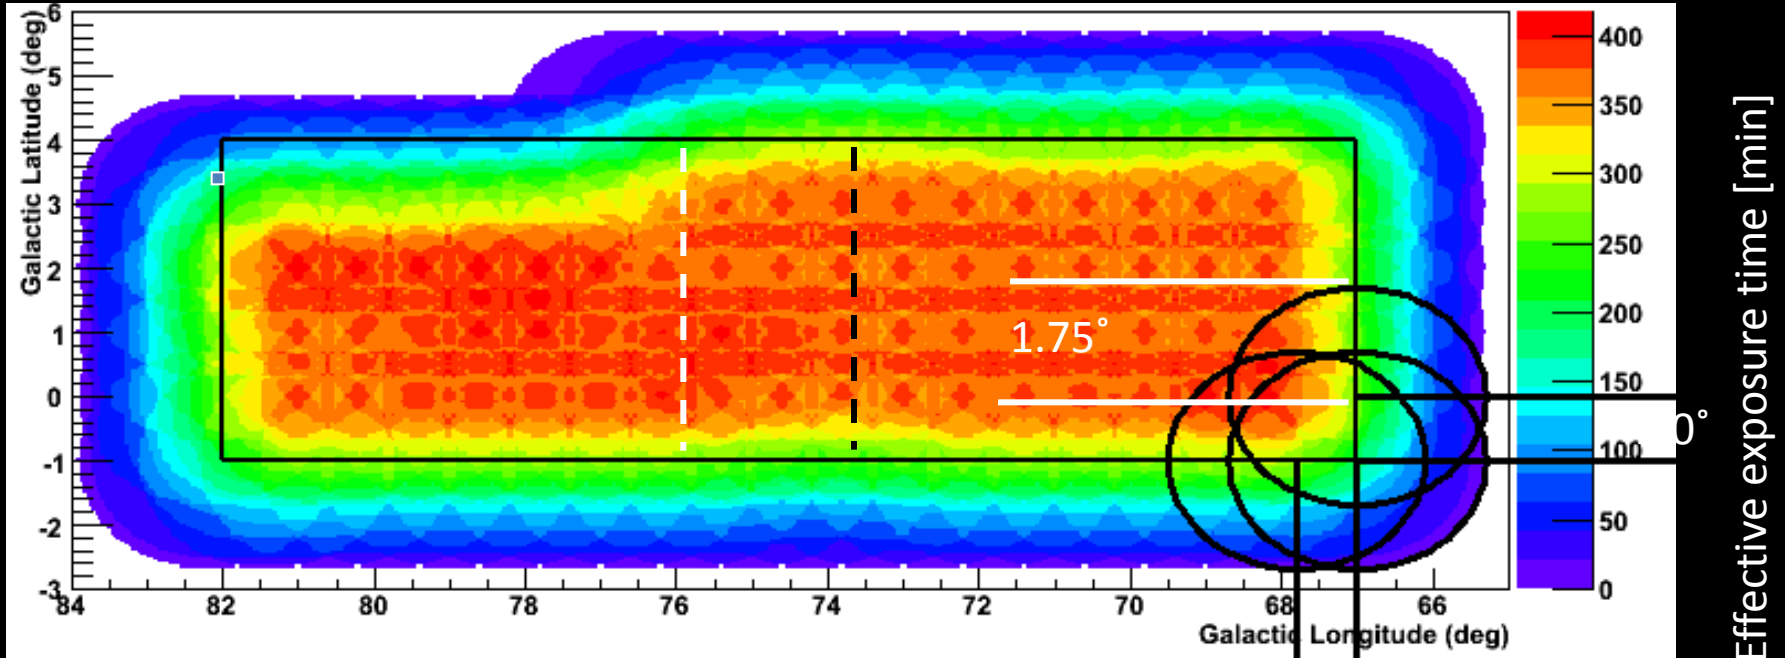

Sensitivity:

- 1% Crab in < 30 hrs
- 10% Crab in < 30 min

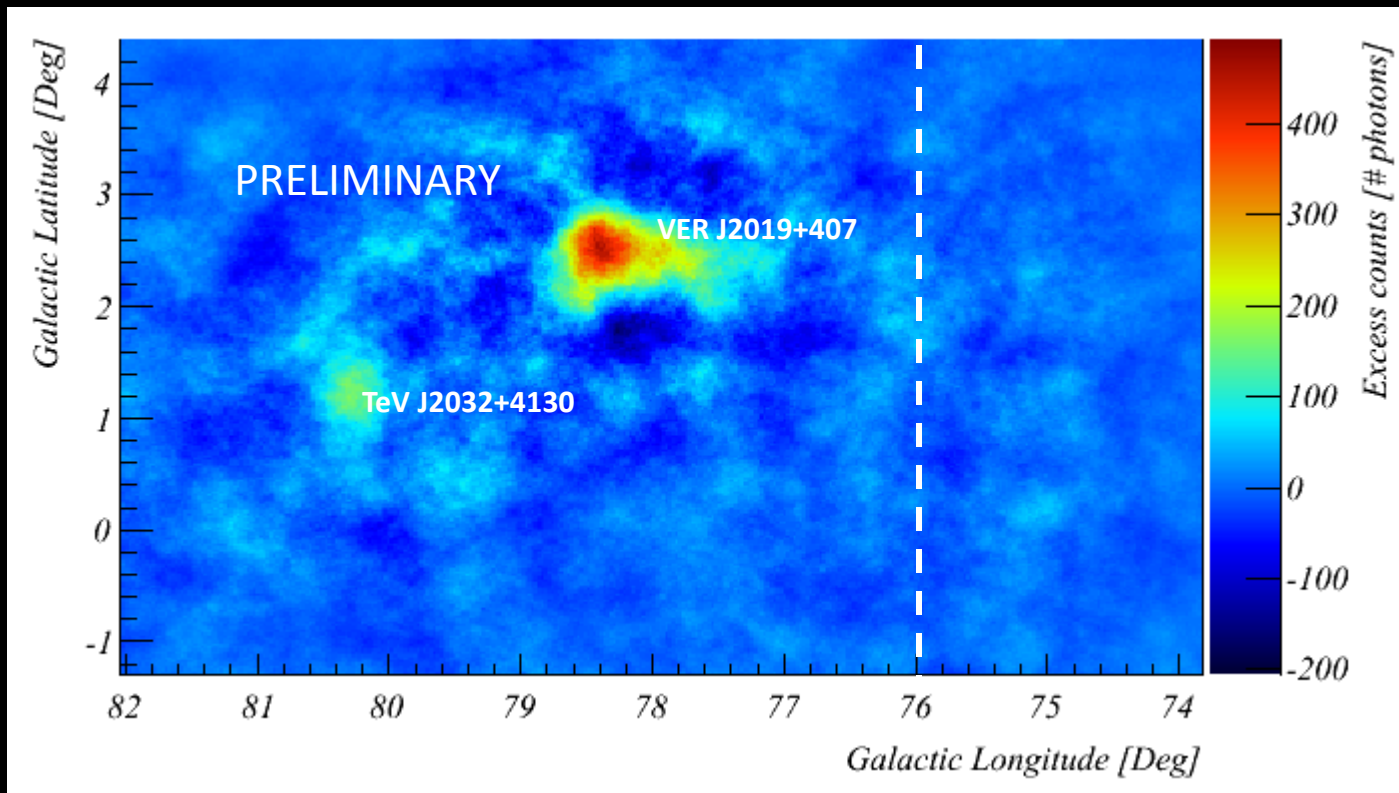

Yearly observing (good weather):

- Dark time ~ 800 hours
- Moonlight ~ 400 hrs additional

Supported by: NSF/DOE/Smithsonian,
SFI(Ireland), NSERC(Canada), STFC
(UK)

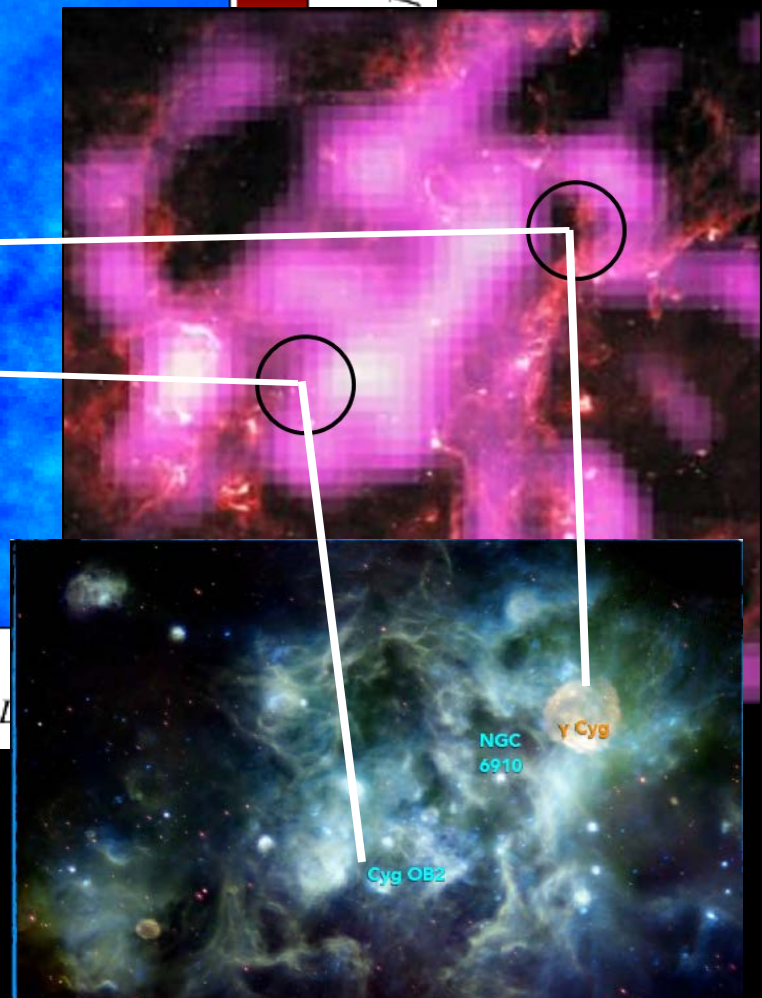

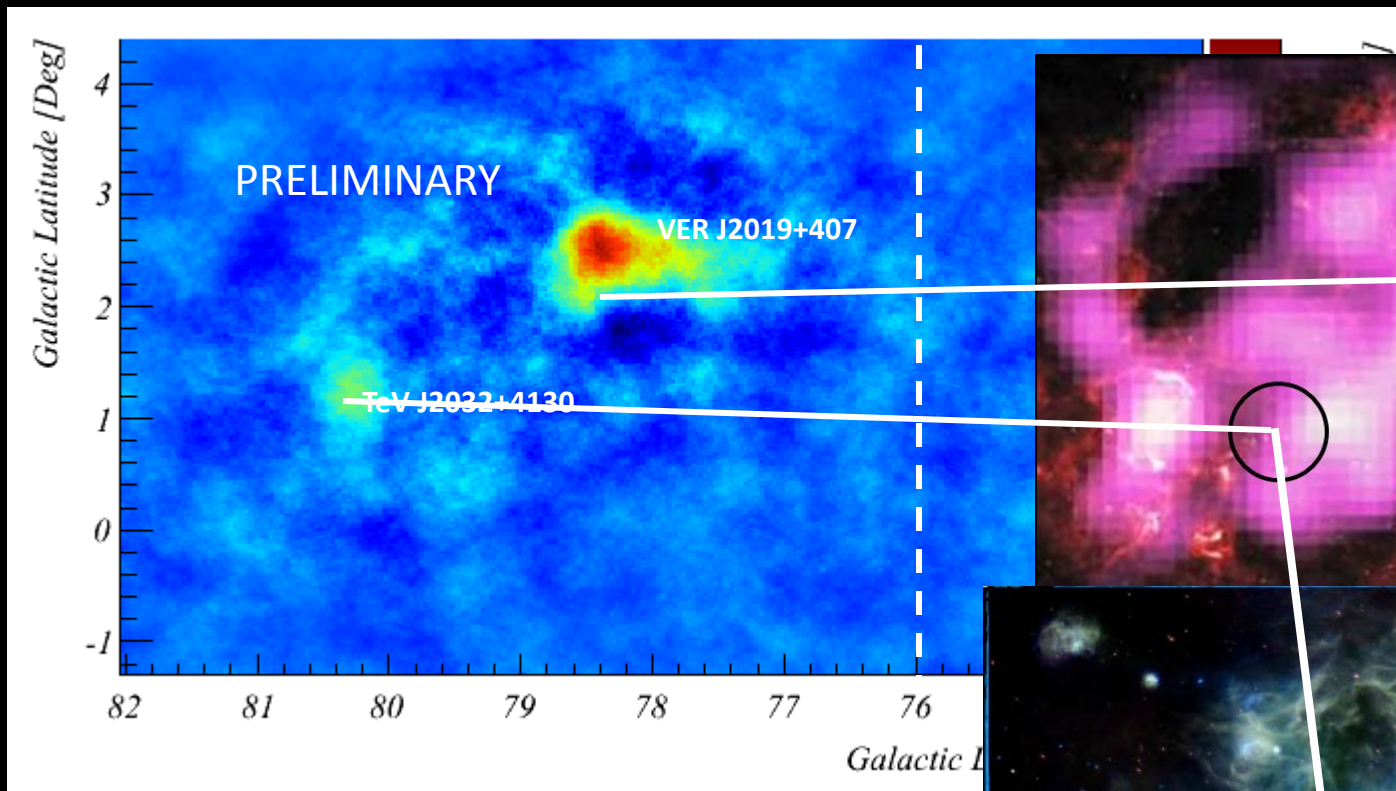

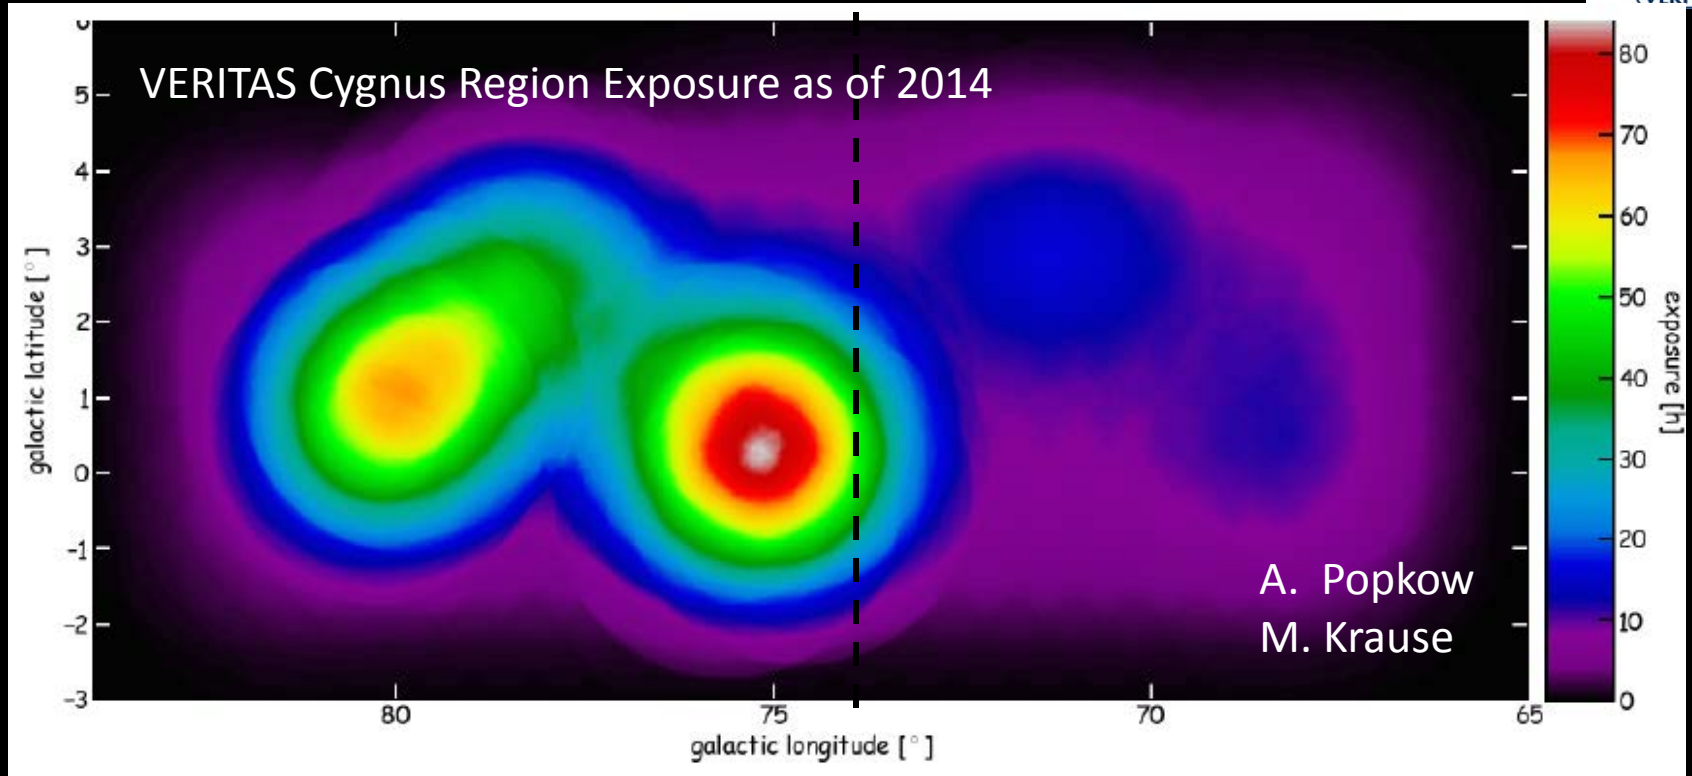

- Survey covers region $67^\circ < l < 82^\circ$, $-1^\circ < b < 4^\circ$
- ~ 6 hrs effective exposure before followup
- ~ 2 yr program

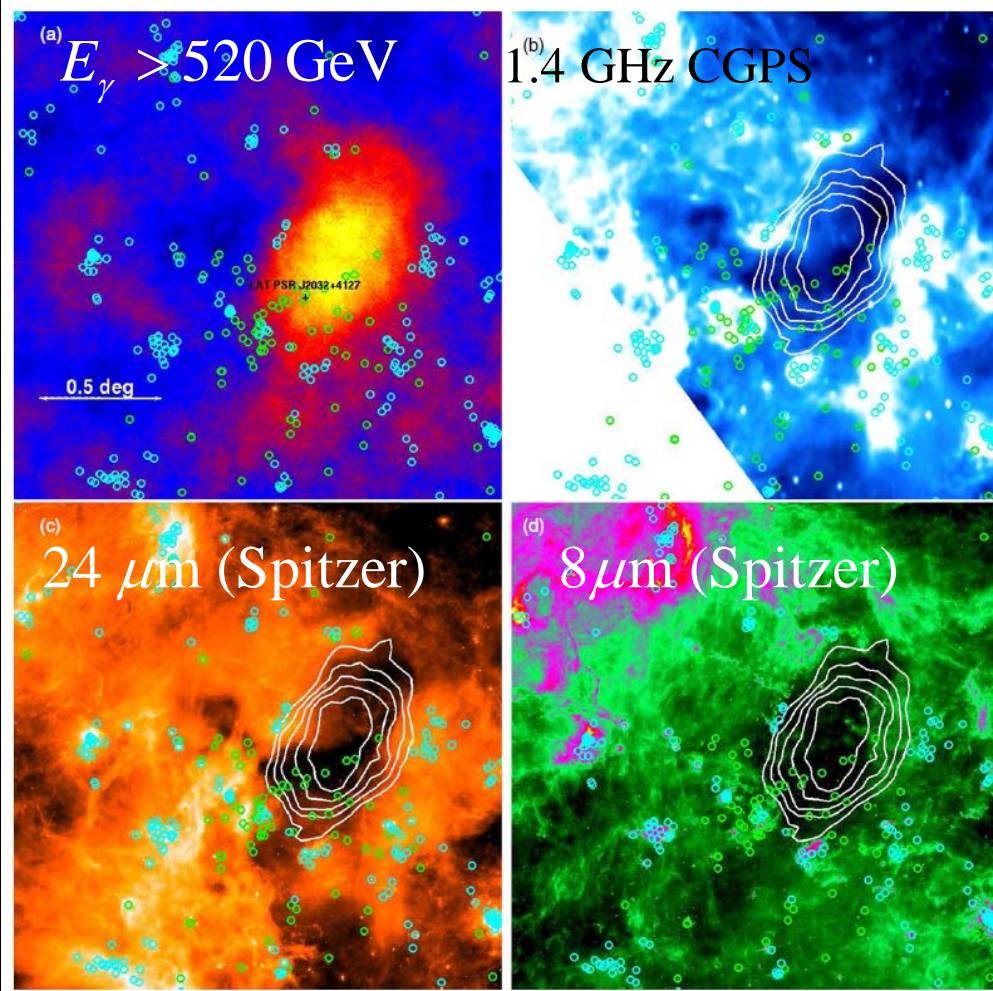

- Based on data through Fall 2009
 - Uneven exposure due to follow-up on VER J2019+407 and TeV J2032
- First shown at 2009 Fermi Symposium

Survey Results (Partial)

- Exposure increased
 - candidate follow-up, independently motivated observations
- Results from new (non-survey) datasets
- Future plans with full set of archival data in survey region

Aliu et al 2014

○ Star forming regions
 ○ OB stars

- VHE gamma-ray emission confined in a “void” of radio, IR emission
- Likely PWN of PSR J2032+4127
 - Faint X-ray PWN consistent w/spin-down properties of pulsar
 - TeV/X-ray luminosity consistent w/PWN expectations
- No significant detection of PWN in Fermi data from 500 MeV – 100 GeV

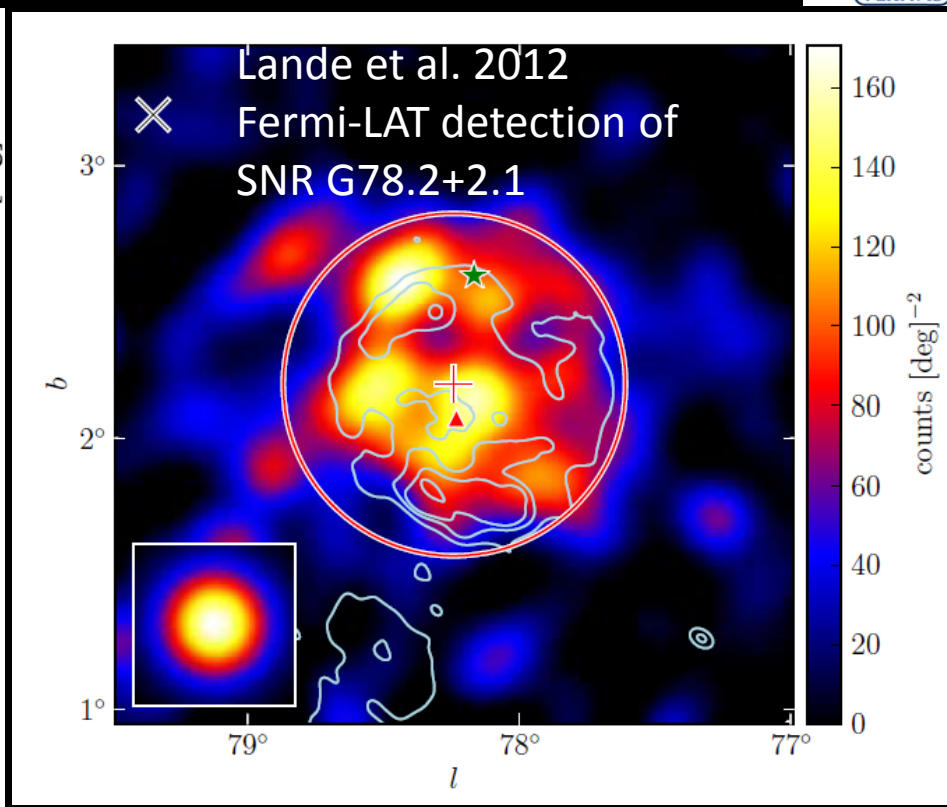

VER J2019+407

Aliu et al 2013

- Emission from SNR?
 - TeV flux consistent with material density
 - Diffuse X-ray emission is thermal

- Offset PWN?
 - Large offset from PSR J2021+4026
 - Leahy et al. 2013—hard X-ray point source with distance consistent with SNR
 - Just outside VER J2019+407 1σ extensions
 - Pulsar? No pulsations seen as yet.

- Same source, energy-dependent morphology?
- Or different origins entirely for emission?

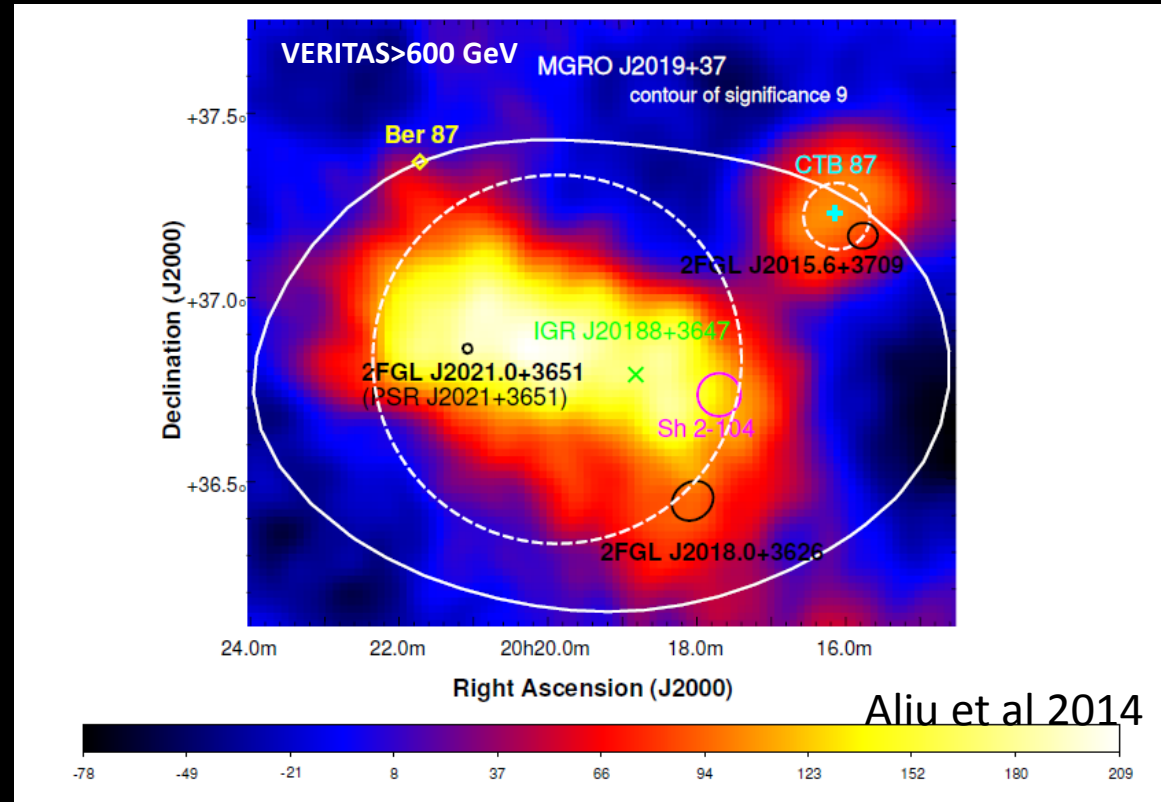

MGRO J2019+307

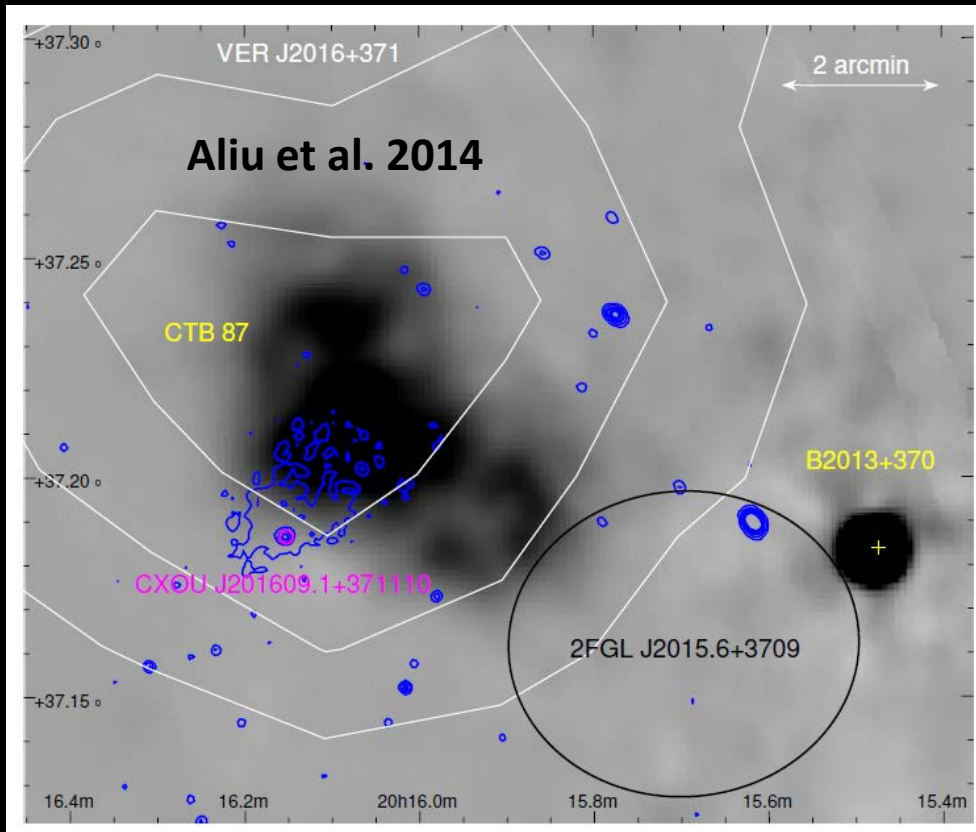

Two sources
discovered:

VER J2016+371
(point)

VER J2019+368
(extended, complex)

- MGRO J2019+307: Brightest diffuse source in Galaxy
- Located towards Cyg OB1, overlaps PSR J2021+3651

Grayscale: 610 MHz GMRT

Chandra: 0.3-7.5 keV

X-ray pulsar candidate

White: VERITAS contours

- Matches up with radio emission (no shell, ID'd as PWN)
 - Multiwavelength properties in line with other VHE PWNe
- Offset radio, TeV PWN: relic population

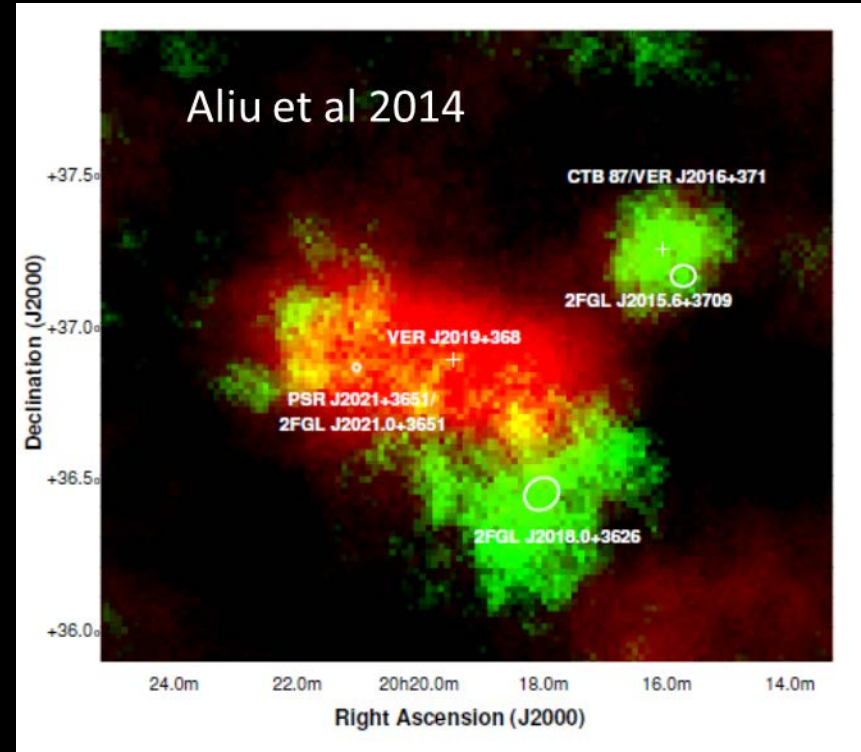

- Consistent with spectral points, flux limits from Milagro and ARGO
- VER J2019+368 clearly main contributor to MGRO J2019+307
- So what is it?

Breaking down VER J2019+368?

Radio

VHE

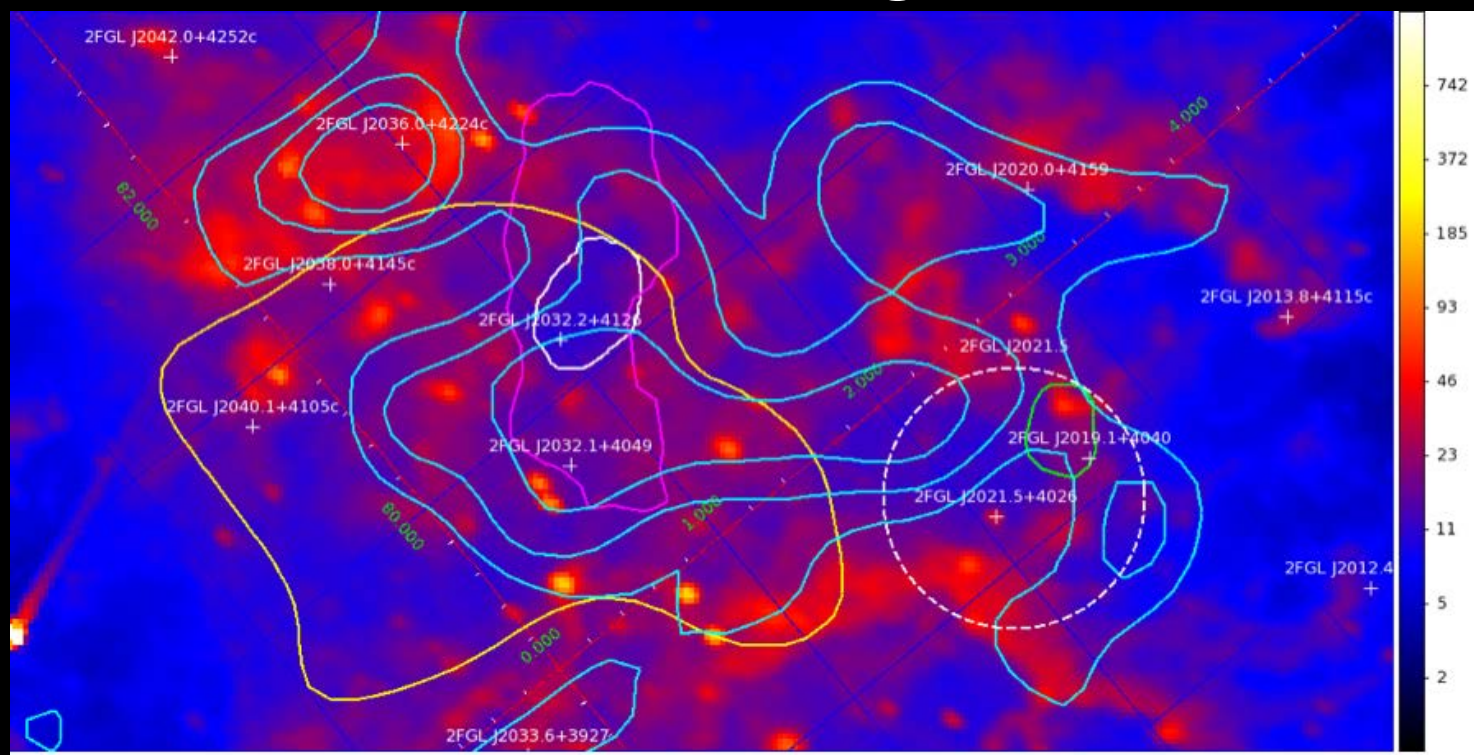

White: VHE contours

TeV PWN of high E-dot pulsar PSR J2021+3651 may account for significant portion of VHE
 However, given likely birth position of pulsar not likely to account for all.

Breaking down VER J2019+368?

The Cocoon: The Big Picture

Yellow: MGRO J2031+41 5σ

White: TeV J2032+4130 5σ (Aliu et al. 2014)

Magenta: ARGO 5σ

Cyan: Cocoon contours (Ackermann et al.)

Green: VER J2019+407 (Aliu et al. 2013)

White dashed: Lande et al. 2012 best fit

Color: 8 micron MSX

- What powers the cocoon (stellar winds in young superbubble environment)?
- What contributes to MGRO J2031+41?
- Important caveats (e.g. distance uncertainties)

The ARGO-YBJ view
at TeV energies ($N_{\text{pad}} \geq 20$)
after reanalysis with the full data

$S_{\text{max}} = 6.1 \text{ s.d.}$
 $\sigma_{\text{ext}} = 1.8^\circ \pm 0.5^\circ$

Di Girolamo SciNeGHE 2014
Bartoli et al. 2014

Spectrum of ARGO J2031+4157: $dN/dE \propto E^{-2.62 \pm 0.27}$

Combined LAT&ARGO spectrum: $dN/dE \propto E^{-2.16 \pm 0.04}$

Milagro points corrected for TeV J2032+4130
ARGO points corrected for nearby sources

The problem of MGRO J2031+41

- ARGO corrects spectrum using IACT fluxes (tricky!) courtesy L. Tibaldo

- Flux discrepancies between techniques
- Don't know cutoffs or how to continue to low energy

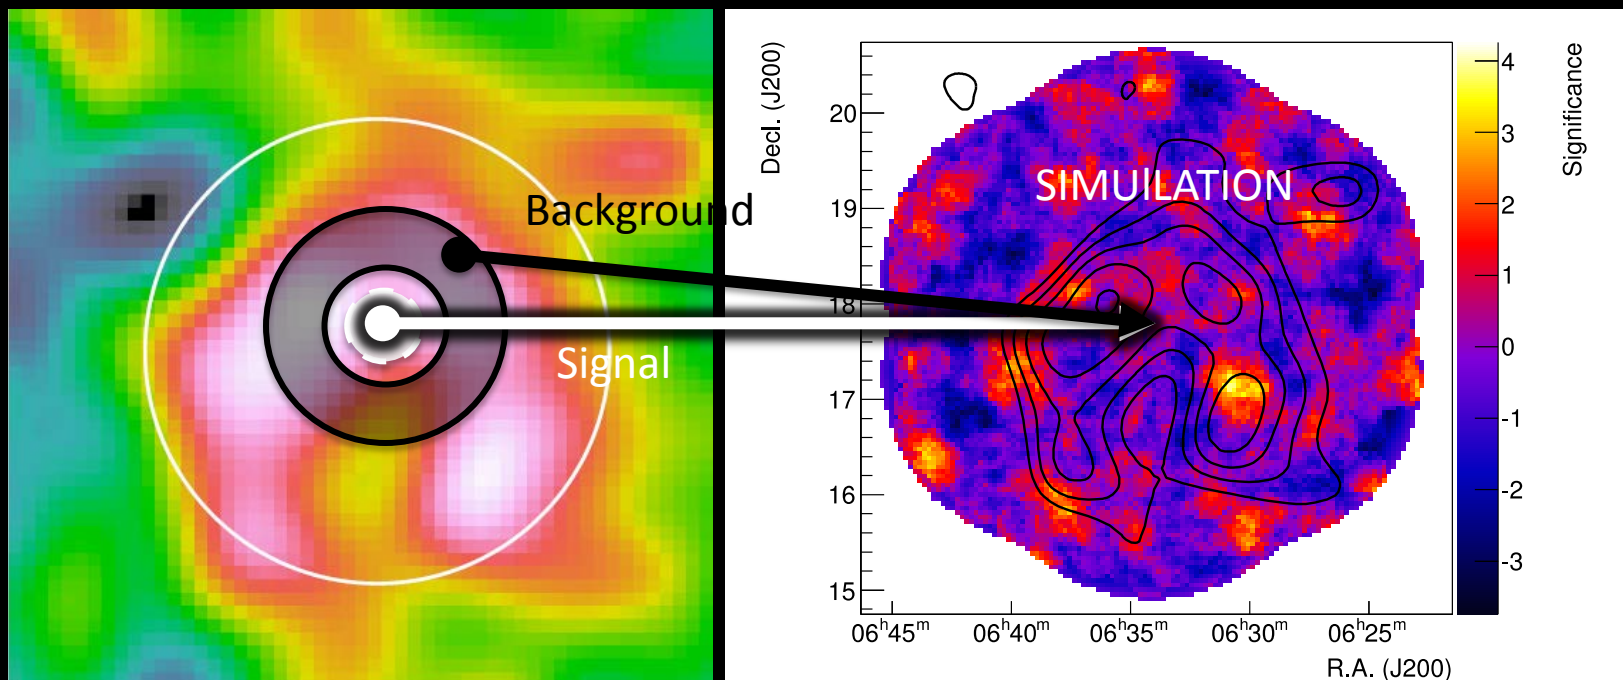

- Wish list

- Better constrain cocoon and gamma Cygni spectra between 500 GeV and 10 TeV
- Better-resolved morphology of all sources, esp. > 1 TeV

VERITAS and the Cygnus Cocoon

- Yesterday upon a stair I met a man who wasn't there. He wasn't there again today, I wish, I wish he'd go away." --- *Antigonish*, Hughes Mearns
- What happens with sources comparable to VERITAS field of view?

Analysis technique matters!

- Maximizes, with respect to a set of free parameters, the “likelihood” that a particular dataset originates from a particular model.

$$L = \frac{N_{\text{exp}}^N e^{-N_{\text{exp}}}}{N!} \prod_{i=1}^N \frac{p(x_i|s)}{N}$$

(s) are a set of free parameters (e.g. flux strength, spectral index)

$p(x_i|s)$ is the probability for a given photon candidate

- In practice, minimize

$$-2 \ln L$$

- Wilk’s Theorem: a test-statistic formed by comparing the likelihood of a “null” hypothesis and a “test” model will be normally distributed

$$TS = -2 \ln \left(\frac{l_{\text{null}}}{l_{\text{test}}} \right)$$

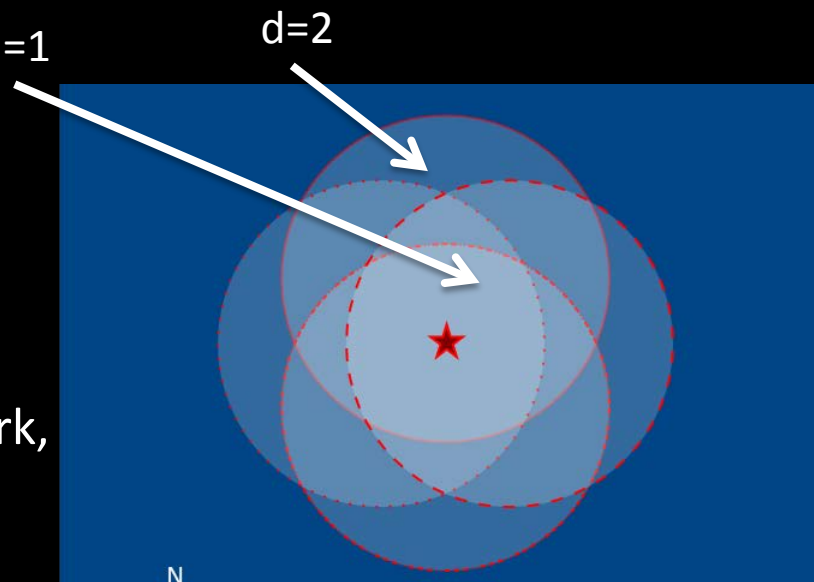

- Permits a statistical significance to be assigned to the signal component of the fit

- “Simultaneous fitting:” group data into datasets d
 - Share a subset of key parameters s across sets
 - Other parameters α_d vary

Physics-driven

$$-2 \ln L = -2 \sum_d \sum_{i=1}^{N^d} \ln p(x_i^d | s, \alpha_d) + 2 \boxed{N_{\text{exp}}^d} + \cancel{2 \ln N^d} \quad \boxed{\text{Extended likelihood term}}$$

- Choice of subdivision driven by
 - **Observation position**
 - Changes in instrument response
- Current version based on RooFIT
 - MINUIT-based likelihood framework,

Expectation for each Dataset

Gamma-ray source

Cosmic-ray background

MSW: templates from gamma-ray simulations

MSW: Templates from "blank field" data

Spatial: Intrinsic source model, convolve with IRFs at each stage of fit

Spatial: templates from "blank field" data---source and cosmic-ray IRFs pre-convolved

- Multi-component model

Key Advantages of MLM

- We fit a model to the entire extended or diffuse source
 - **Higher Sensitivity:** Signal/background ratio for any category controlled by flux of **full source** (or fraction of source in field of view).*
 - **Reduced Trials Factors:** Test coarse grid of extended source model positions rather than checking at many (correlated) points within the extended source.
- **Powerful diagnostic tools** to address systematic errors from modeling
- Technique **naturally extends to multiple overlapping sources**
 - Can test assumptions
- Simultaneous fitting approach provides **potential extension to multi-instrument datasets** (Fermi, HAWC)

How much does it help?

Toy model simulation of observations in the Cygnus region between 500GeV-1TeV.

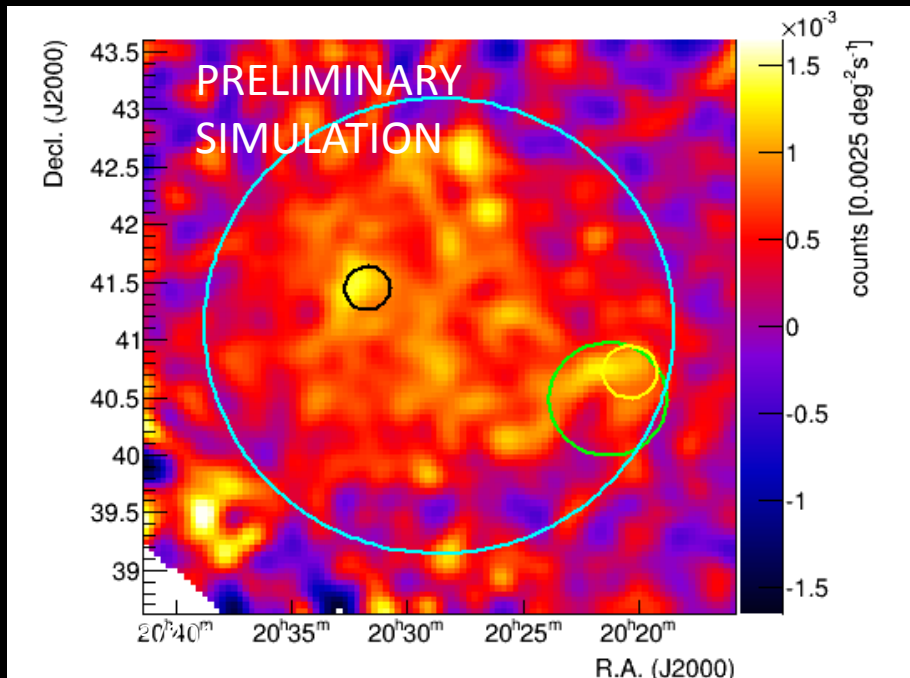

Source	MLM Sqrt(TS)	RBM Significance (nominal position)
TeV J2032+4130	4.47	3.33
VER J2019+407	2.82	3.6
Cocoon (2°Gaussian)	33.2	-0.05
Gamma Cygni	5.1	3.43

MLM

Shows evidence of extended emission

RBM

No evidence of extended emission

- Active work to repeat the standard analysis of all VERITAS data in Cygnus region
 - Survey proper
 - Follow-up data
 - Target date: Summer 2015 for first preliminary results
- 3D MLM approach will provide a significantly different view of this same dataset
 - Target date: by the end of 2015

Conclusions

- The Cygnus region above a GeV remains science-rich, challenging, and full of mysteries
 - E.g. the “Cygnus cocoon”
 - Evidence for CR acceleration in superbubbles?
 - A snapshot of recently escaped or re-accelerated cosmic rays?
 - VERITAS and HAWC both have a critical role to play
- VERITAS is rising to the challenges posed by this region
 - Stay tuned!

BACKUP SLIDES

VER J2016+371 continued

Black: 2FGL 2015.6+3709
 Red: 3FGL 2015.6+3709
