## $4^{\text {TH }}$ FAMILY QUARKS AT ATLAS <br> V. Erkcan Ozcan University College London

Beyond the 3SM generation at LHC era WS, CERN, Sept. 04, 2008

## OUTLINE / MOTIVATION

- LHC scheduled to have first protons on Sept. 10, 2008.
- CM energy 7x larger than Tevatron, low x, gluon pdfs significant $=>$ pair production of heavy quarks...
- Recent exciting results from $\mathrm{CDF}=>$ the first $\sim 100 \mathrm{pb}^{-1}$ of data will be very interesting.
- $\mathrm{u}_{4} / \mathrm{d}_{4}$ discovery potential at ATLAS:
- ATLAS TDR: $\mathrm{q}_{4}$ mixing with $\mathrm{t} / \mathrm{b}$
- Recent results: $\mathrm{q}_{4}$ mixing with $\mathrm{u} / \mathrm{d} / \mathrm{s} / \mathrm{c}$

- Not in this talk - other heavy quark searches: isosinglets, FCNCs, ...

| Tracking | $\|\eta\|<2.5$ |
| :---: | :---: |
| EM Cal. | $\|\eta\|<3.2$ |
| Had. Cal. | $\|\eta\|<\sim 4.9$ |

|  | Start-up of LHC | Ultimate goal |
| :--- | :---: | :---: |
| Electromagnetic energy uniformity | $1-2 \%$ | $0.5 \%$ |
| Electron energy scale | $\sim 2 \%$ | $0.02 \%$ |
| Hadronic energy uniformity | $2-3 \%$ | $<1 \%$ |
| Jet energy scale | $<10 \%$ | $1 \%$ |
| Inner-detector alignment | $50-100 \mu \mathrm{~m}$ | $<10 \mu \mathrm{~m}$ |
| Muon-spectrometer alignment | $<200 \mu \mathrm{~m}$ | $30 \mu \mathrm{~m}$ |
| Muon momentum scale | $\sim 1 \%$ | $0.02 \%$ |

$4^{\text {TH }}$ GEN. QUARKS IN ATLAS TDR

- Pair production of $u_{4}$ and $d_{4} s$ and possibly a heavy quarkonium state $\eta_{4}$ was studied.
- Mixing assumed to be dominantly with $3^{\text {rd }}$ generation
- Democratic mass matrix (DMM) approach taken; thus assuming $\left|\mathrm{m}_{\mathrm{u} 4}-\mathrm{m}_{\mathrm{d} 4}\right| \sim$ few $\mathrm{GeV}<\mathrm{m}_{\mathrm{w}}$.
- But results obtained for "generic" heavy quarks that would decay as $u_{4} \rightarrow \mathrm{~Wb}$ and $\mathrm{d}_{4} \rightarrow \mathrm{Wt}$.
- Two mass values: $320 \mathrm{GeV}, 640 \mathrm{GeV}$

## TDR ANALYSES

- $\mathrm{u}_{4} \mathbf{u}_{4}$ and $\mathrm{d}_{4} \mathrm{~d}_{4}$ analyses quite similar, though one involves the intermediate step of recontructing tops.
- Primary jets (direct daughters of $\mathrm{u}_{4}$ ) at high $\mathrm{P}_{\mathrm{T}}$
- One of Ws in leptonic channel (with isolated $\mu$ or e), all others in hadronic channel
- b-tagging/b-veto as expected in the final state
- From each event only one q4 finally reconstructed, the fact that one expects two objects of same mass is not exploited.
- Main background from tt pair production.

## TDR CONCLUSIONS

- With $\mathrm{O}\left(\mathrm{few} \mathrm{fb}^{-1}\right)$ enough for discovery.
- Next step? "Full" analysis, "recent" software...

## A LOOK AT $4 \times 4$ CKM

- Take the measurements of the quark mixings from PDG and apply unitarity constraints for $4 \times 4$ CKM:

$$
\mathrm{CKM}_{4 \times 4}=\left[\begin{array}{cccc}
0.97377 \pm 0.00027 & 0.2257 \pm 0.0021 & 0.00431 \pm 0.00030 & <0.044 \\
0.230 \pm 0.011 & 0.957 \pm 0.095 & 0.0416 \pm 0.0006 & <0.46 \\
0.0074 \pm 0.0008 & 0.0406 \pm 0.0027 & >0.78 & <0.47 \\
<0.063 & <0.46 & <0.47 & >0.57
\end{array}\right]
$$

- Assume : $\left|V_{d_{4} u}\right|^{2}+\left|V_{d_{4} c}\right|^{2} \gg\left|V_{d_{4} t}\right|^{2}$

$$
\left|V_{u_{4} d}\right|^{2}+\left|V_{u_{4} s}\right|^{2} \gg\left|V_{u_{4} b}\right|^{2}
$$

- The final state would be: $\mathrm{pp} \rightarrow \mathrm{q}_{4} \mathrm{q}_{4} \rightarrow \mathrm{WjWj}, \mathrm{j}=$ light jet - Look at semileptonic channel: (lv)j(jj)j

## EVENT GENERATION

- Signal events with CompHep 4.4.3. 12k signal events each for two choices of mass.

| $\mathrm{m}_{\mathrm{q}^{4}}(\mathrm{GeV})$ | 500 | 750 |
| :---: | :---: | :---: |
| $\Gamma_{\mathrm{q}^{4}}(\mathrm{GeV})$ | $8.2 \times 10^{-3}$ | $2.8 \times 10^{-2}$ |
| $\sigma_{\mathrm{pp} \cdot d \mathrm{dd4}}(\mathrm{pb})$ | 2.63 | 0.25 |

- Background events with MadGraph 3.95. A total of $280+\mathrm{k}$ events at various QCD scales and jet $\mathrm{P}_{\mathrm{T}}$ cuts.
- PDF=CTEQ6L1. Pythia 6.23 for parton showering, hadronization, etc.
- ATLFast fast simulation for detector effects.

## BACKGROUNDS

- Initially considered WbWb (mainly tt ) and ( $\mathrm{W} / \mathrm{Z}$ )Wjj.
- However $\mathrm{WbWbj}(\mathrm{ttj})$ has similar xsec to WbWb and satisfies selection criteria with higher efficiency.
- WbWb is the dominant background.
- tt2j xsec $\sim 4$ times smaller than $t t j$ in the relevant jet $P_{T}$ range. Neglected.
- No matching was done, WbWb and WbWbj simply added conservatively.

## EvENT SELECTION

| Selection Criterion | $\varepsilon_{\text {sig. }}{ }^{\mathrm{m}=500}$ | $\varepsilon_{\text {sig. }} \mathrm{m}=750$ | $\varepsilon_{\text {bkg }}{ }^{\text {tij }}$ |
| :---: | :---: | :---: | :---: |
| isolated e/ $\mu, \mathrm{P}_{\mathrm{T}}>15 \mathrm{GeV}$ | 32 | 32 | 29 |
| $4+$ jets, $\mathrm{P}_{\mathrm{T}}>20 \mathrm{GeV}$ | 86 | 84 | 84 |
| 4 hardest jets: b-tagging veto | 92 | 90 | 33 |
| possible neutrino solution | 75 | 71 | 76 |
| $\mathrm{m}_{\mathrm{ij}}{ }^{\mathrm{W}}<200 \mathrm{GeV}$ | 50 | 44 | 75 |
| 2 hardest jets: $\mathrm{P}_{\mathrm{T}}>100 \mathrm{GeV}$ | 94 | 98 | 35 |
| $\left\|\Delta \mathrm{mWj}^{\mathrm{q}^{4}}\right\|<100 \mathrm{GeV}$ | 56 | 49 | 50 |
| $\varepsilon_{\text {total }}$ | 5.0 | 3.6 | 0.8 |

## Kinematic Variables

- Primary jets at high $\mathrm{P}_{\mathrm{T}}$, very loose cuts.
- If backgrounds are found to be more significant in data, $\mathrm{P}_{\mathrm{T}}{ }^{\text {miss }} \& \mathrm{P}_{\mathrm{T}}{ }^{\text {lepton }}$ cuts.
- Ws can be reconstructed from single jet (will recover the long tail in $\mathrm{m}_{\mathrm{ij}}$ distribution). $=>$ Recently shown to have excellent potential at ATLAS for $P_{T}{ }^{W}>\sim 250 \mathrm{GeV},+$ can use jet substructure.

## RESULTS

- From each event two $q_{4}$ candidates.
- Dominant background from WbWbj, other backgrounds an order of magnitude lower.

## FIT - WHY?

- Obtain a blind method to identify the signal above the background.
- Blind = With essentially zero human input. Define one procedure to apply and irrespective of the mass of the $q_{4}$ candidate, the fit tells you the result. Fit should be robust, ie. no tuning of starting parameters for different $\mathrm{q}_{4}$ masses.
- Backgrounds are extracted from data, ie. no dependence on background MC systematics. Also robustness against backgrounds not considered.

## Fit - How?

- Breit-Wigner for the signal component.
- Crystal Ball for the sum of backgrounds:

Generated Toy Spectrum - Landau is a good empirical definition for mass of objects obtained by
4-momenta have c
Take two objects y
masses (whose dis
to each other. You

## Fit Results

- Extract signal and background by integrating the fit within $\pm 2 \Gamma$ of signal BW.
- Divide by two to get number of events.
- Fit in very good agreement with real inputs.
- Significance computed as s/sqrt(s+b).
- Pseudo-MC to check whether reported significances.

|  | 500 GeV | 750 GeV |
| :---: | :---: | :---: |
| Luminosity | $1 \mathrm{fb}-1$ | $10 \mathrm{fb}^{-1}$ |
| Signal | 192 | 134 |
| Background | 224 | 226 |
| Significance | 9.2 | 7.1 |

## Discovery Range

- Reach plot obtained by: integrating BG fit function, extrapolating for signal efficiency and calculating the x -sec as function of mass.

## CONCLUSION

- Recently many similar analyses (ex: search for isosinglet quarks in E6) went through the fullsimulation studies and ATLFast results were found to be not too optimistic.
- Expect the same for 4th-family quarks. Also note that not all ideas exploited yet.
- ATLAS has clear potential for $5 \sigma$ discovery even with the first $\sim 100 \mathrm{pb}-1$ of data (for $\mathrm{m}_{\mathrm{q} 4} \sim 400-500 \mathrm{GeV}$ ).

## BACK-UP SLIDES

## HADRONIC VBS: 1 OR 2 JETS

- At high enough $\mathrm{P}_{\mathrm{T}}$, hadronic VB starts to create a single jet.
- So start by looking at each event for jets with mass close to $\mathrm{W} / \mathrm{Z}$ ?

Yes: This jet is the VB candidate. Apply cut on jet substructure.

No: Try reconstructing your W candidates from pairs of jets.

Plot for $\mathrm{k}_{\mathrm{T}}$ jets with $\mathrm{R}=0.6$.

## JET STRUCTURE

- $\mathrm{k}_{\mathrm{T}}$ merging intrinsically ordered in scale.
- Undo last merging: Get the Y-scale at which the jet would split into two subjets.
- Y-scale $\sim \mathrm{O}\left(\mathrm{m}_{\mathrm{VB}} / 2\right) \sim \mathrm{k}_{\mathrm{T}}$ of one subjet wrt. other
