

**Algorithms and Software
for
Hardware Alignment Systems**

Pedro Arce (CIEMAT)

LHC Detector Alignment Workshop

Outline

- Optical alignment
 - The CMS optical alignment system
 - The problem of optical alignment and how to solve it
 - COCOA
- Effect of misalignment in the reconstruction
- Alignment with tracks
- Commonalities and difference of the several alignment softwares

The CMS optical alignment system

CMS elements suffer movements and deformations from magnetic field, gravity and temperature (\approx several mm)

We need precision $\approx 150 \mu\text{m}$:
Monitor Muon Chambers relatively among them

- Align. internal Muon Barrel
- Align. internal Muon Endcap

Monitor Muon Ch. w.r.t. Tracker

- Align. Muon \leftrightarrow Tracker ('Link')

Monitor Tracker Sensors relatively among them

- Align. Internal Tracker

4 subsystems with quite different hardware

The problem

SIMULATION:

- **Error propagation:**

- Calculate how much the errors of the calibrated parameters and of the measurements affect the errors of the parameters we want to measure

- **Redundancies:**

- How much the errors change if some measurement disappears

-

- **Range:**

- When a measurement will get out of the range of the measuring device if some objects move

The problem (II)

RECONSTRUCTION:

- Optical system takes measurements (2D sensors, 1D sensors, tiltmeters, distancemeters)

⇒ results are not what expected by extrapolating measured and calibrated parameters. **Why?**

- Wrong rotation / position of some objects
- Wrong internal calibration of some objects
 - wedge of a splitter
 - internal calibration of a distancemeter
 - deviation when traversing a sensor
 - ...
- **Software is the same for Simulation and Reconstruction**
 - Only difference: for Simulation measurement is ideal, for Reconstruction measurement is real

How to solve it

➤ Get the equations of how each measurement depends on all these parameters

- positions, rotations and internal parameters

$$M_1 = f_1(p_1, p_2, \dots, p_m)$$

$$M_2 = f_2(p_1, p_2, \dots, p_m)$$

...

$$M_n = f_n(p_1, p_2, \dots, p_m)$$

$M_1, \dots, M_n = \text{Measurements}$

$p_1, \dots, p_m = \text{parameters (known and unknown)}$

f_i are non linear equations

❖ You know the measurements and some calibrated parameters, you need to know the missing ones

⇒ Solve the system of equations: **Non-linear least squares fit**

- To solve a system of equations, you do not have to know the equations

How to solve it (II)

- **Only derivatives are needed**

⇒ **Get the derivatives with a numerical method**

- Reproduce a measurement with initial parameters (e.g. propagate a laser until the sensor)
- Move a parameter and see how the measurement value changes
- Repeat n times moving $1/2^i$, until it converges

Total CMS alignment system: 40000 parameters

⇒ **big and sparse matrices**

⇒ **sparse matrix library (meschach C library)**

Cms Object-oriented Code for Optical Alignment

◆ General purpose software to simulate and reconstruct optical alignment systems composed of any combination of

laser, x-hair laser, source, lens, pinhole, mirror, plate splitter, cube splitter, rhomboid prism, optical square, sensor2D, sensor1D, COPS, distancemeter, distance target, tiltmeter, 'user defined'

- Each object has internal parameters (planarity of a mirror, wedge between plates of a plate splitter, internal calibration of COPS...)
 - 'user defined': you can tell COCOA how much light shifts and deviates in the ASCII file
- Reconstructs positions and angles of the objects from the measurement values
- Propagates the errors of the measurements and calibrations (including correlations)

COCOA

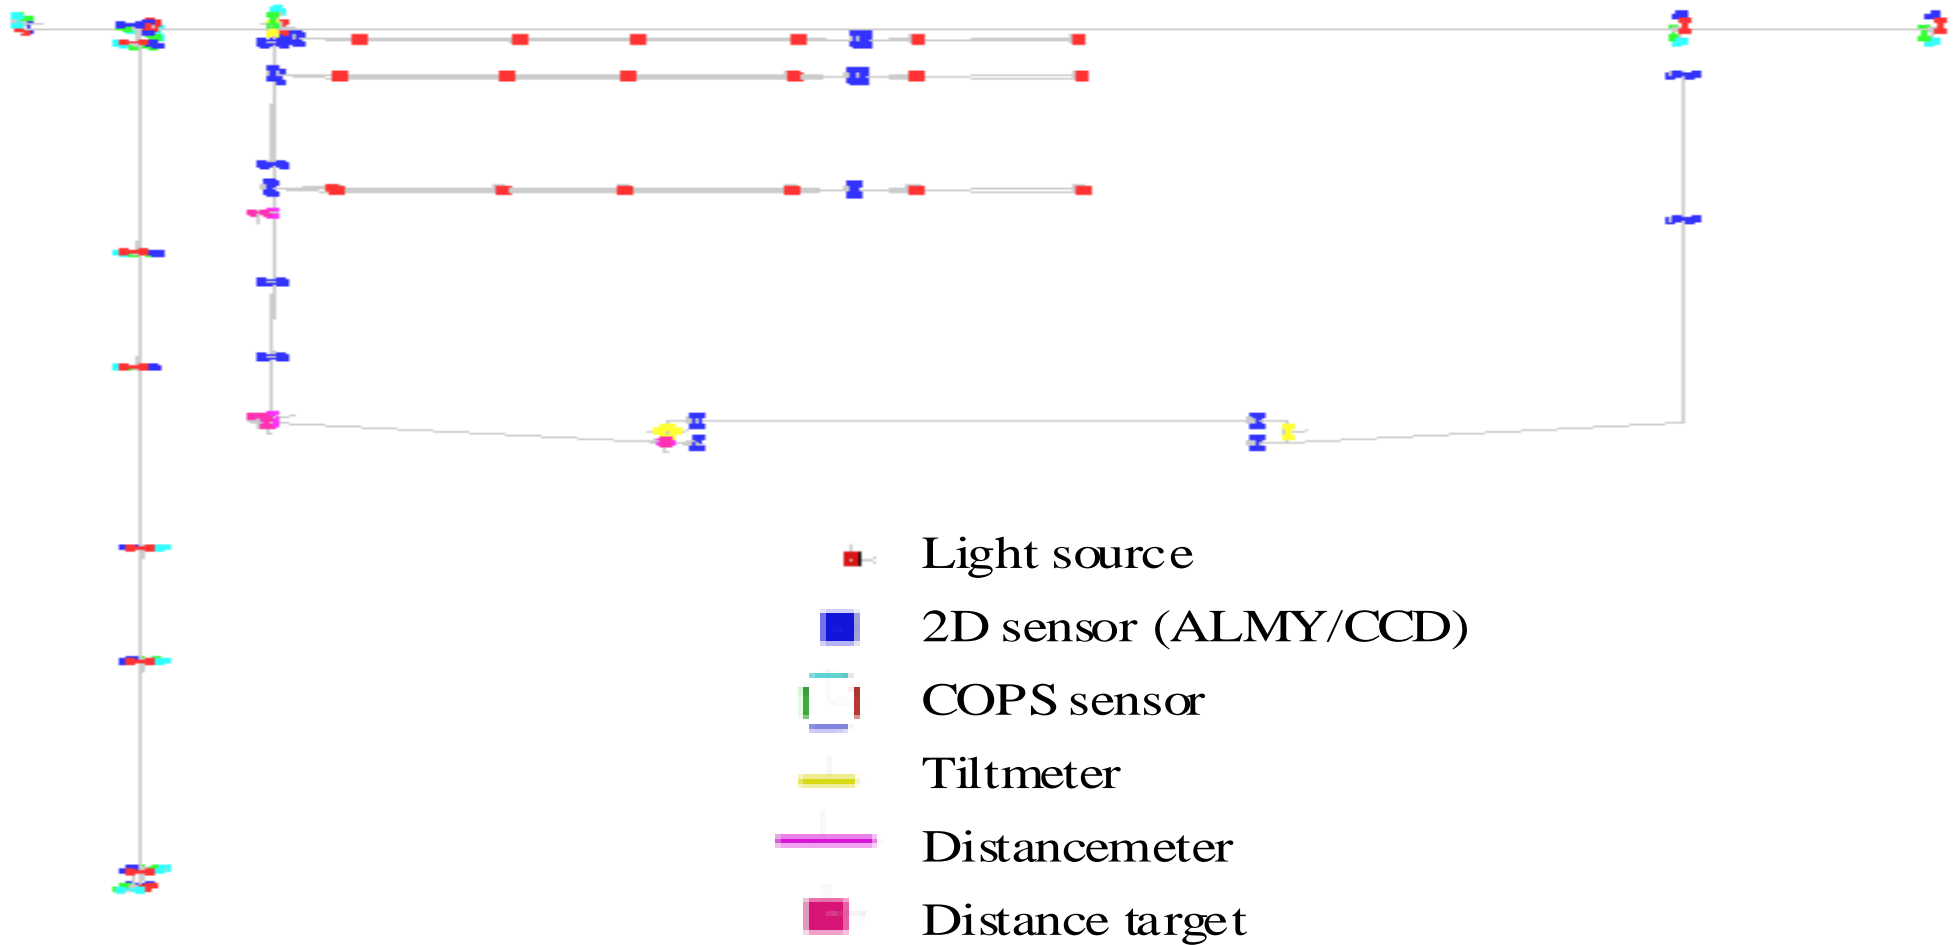

- Interactive 3D view
 - VRML (Virtual Reality Modeling Language)
 - IGUANA (Interactive Graphics for User ANALysis)
- Geometry
 - ASCII files
 - ROOT tree files
- Calibrated data can be read from Oracle DB to update data on file
- Interface with DAQ measurements
 - ASCII files
 - ROOT tree files
- Calibrated data can be read from Oracle DB to update data on file
- Output
 - ASCII file
 - Oracle DB
- ❖ Fully integrated with CMS software
 - Output interchangeable between COCOA and alignment with tracks sw

Full ISR setup in COCOA

(interactive 3D VRML view)

COCOA

- **Documentation:**

- † Primer

- † User's Guide

- † Advanced User's Guide

- † Two examples explained with detail

- † dOxygen reference manual

COCOA

▪ How it works:

- Describe the system in an input ASCII file
 - Also from an XML file
 - Select which parameters are unknown and which are known
 - For the known one write the values
 - They can also be read from an Oracle DB
 - Input the measurements
 - They can also be read from an ASCII file or a ROOT tree
- COCOA provides **best values for unknown parameters** (positions/rotations/internal parameters) compatible with measurements and **propagate the errors** from the measurements and the known parameters to the know and unknown parameters
- Also correct known parameters if current values do not provide a good fit

An example input file

```
// system composed of one laser, one periscope that  
holds a plate splitter and a mirror and two 2D  
sensors.
```

GLOBAL_OPTIONS

```
report_verbose 2  
save_matrices 0  
length_error_dimension 2  
angle_error_dimension 2
```

PARAMETERS

```
pos_laser 0  
posZ_periscope 1  
posZ_sensor 1.1  
err_pos 100  
err_ang 100  
prec_sens2D 5
```

SYSTEM_TREE_DESCRIPTION

```

Use of COCOA

- Several test benches
- Several design studies
- Simulation full CMS Link alignment system (3000 parameters)
- Simulation full CMS Muon Endcap system (6500 parameters)
- Reconstruction of ISR test (test of a full CMS muon alignment halfplane)
- Reconstruction of MTCC test (fraction of final design of CMS, with B field)
- Will be used in 2007 for final CMS hardware alignment systems

Muon Endcap Alignment: Full simulation view

Reconstruction of ISR test

- ‘Proof of concept’ test of CMS alignment system: one full half-plane

- ❖ Barrel

- 18 forks (4 light sources each)
- 3 double cameras
- 3 single cameras on MAB+z
- 120 measurements

- ❖ Endcap

- 2 x-hair lasers
- 7 COPS
- transfer plate with 2 COPS
- 1 COPS on MAB +Z
- 1 COPS on fake MA -Z
- 47 measurements

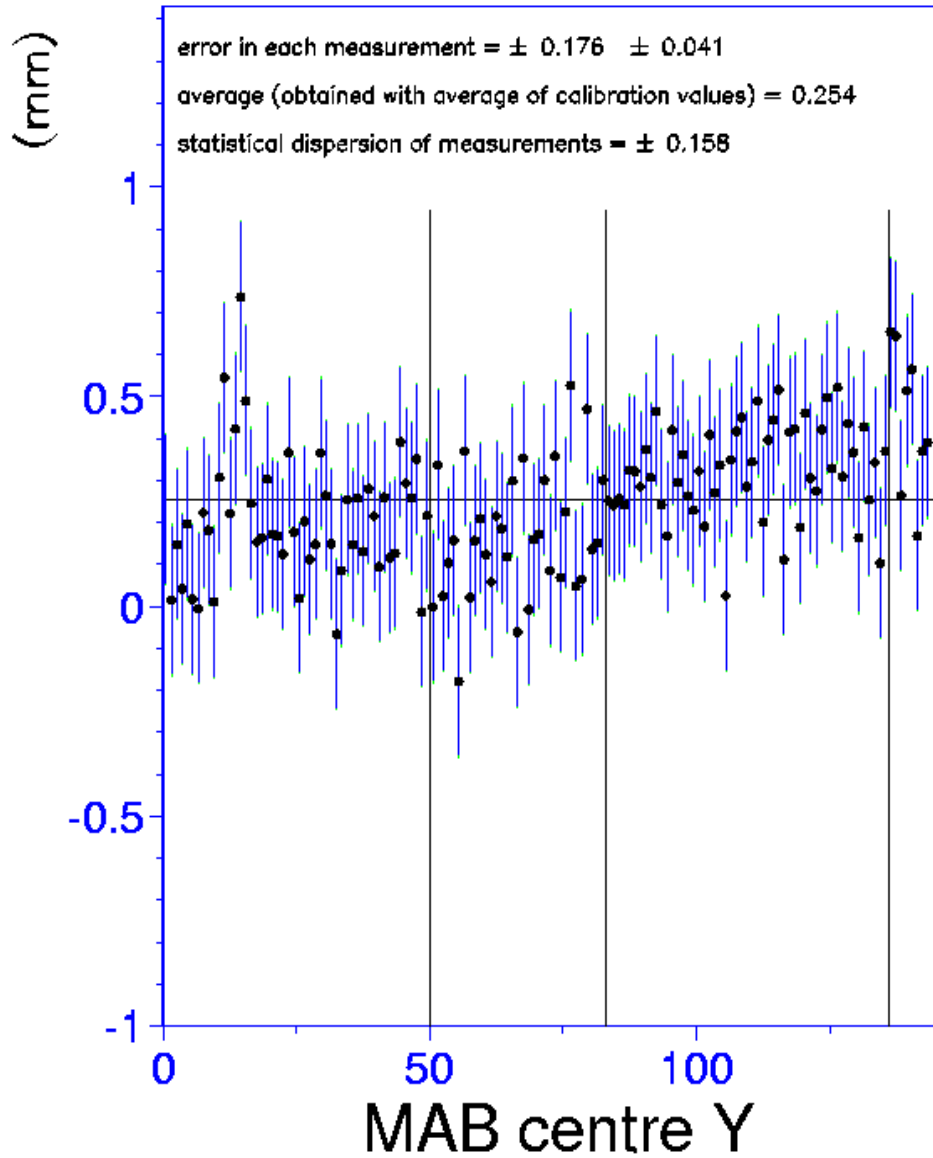

- ❖ Link

- 2 laserboxes
- laser level
- 10 2D sensors
- 2 tubes
- 4 distancemeters
- 4 tiltmeters
- 312 measurements

- Input object parameters from calibrations
- Input object positions from survey
- Input measurements collected during August and September 2001

August

Link - survey measurement

September

Link - survey measurement

Time and memory consumption

Full CMS Link alignment system (2865 parameters):

- **31 minutes** in Pentium III 850 MHz
 - Memory: **590 Mb**
 - Due to the size of matrices
 - Time and memory scales as $\sim(\#\text{param})^2!$
- ⇒ we cannot simulate full CMS ($\sim 40\text{k}$ params)

Time and memory consumption

- ☺ Several solutions under study:
- **Diminish the number of parameters**
 - Many parameters have a negligible effect in the final result
 - Needs a thorough testing to avoid biasing
 - **Split the system in N parts**
 - There is no really independent subsystem though...
 - **Use other library packages**
 - Millipede II, ...
