## WHAT IS CRYPTOGRAPHY?

Cryptography (From Greek means "secret writing") is the practice and study of techniques for secure communication in the presence of third parties.

## ENGRYPTION ALGORITHMS

* Classified as symmetric and asymmetric classes.
* Symmetric
algorithms
are
a
class of algorithms for cryptography that use the same cryptographic keys for both encryption of plaintext and decryption of ciphertext. The keys may be identical or there may be a simple transformation to go between the two keys. The keys, in practice, represent a shared secret between two or more parties that can be used to maintain a private information link.

## ENGRYPTION ALGORITHMS

x Asymmetric algorithms, is a class of cryptographic algorithms which requires two separate keys, one of which is secret (or private) and one of which is public. Although difference, the two parts of this key pair are mathematically linked. The public key is used to encrypt plaintext or to verify a digital signature, whereas the private key is used to decrypt ciphertext or to create a digital signature.

## ENGRYPTION ALGORITHMS

$\times$ As it is widely known for protection of the information generally symmetric block algorithms shall be applied, as the open key systems speed is quite low.

## SYMMETRICAL CRYPTOSYSTEM

## SYMMETRICAL GRYPTOSYSTEM

* In order to cover the open text structure the most effective way is to apply for two transformations: confusion and diffusion.
* Confusion is the transformation, the goal of which is to cover the connection among the keys and the ciphertext, and the goal of the diffusion is to render each symbol of the ciphertext dependent onto all the symbols of the open text, which would enable us to cover the open text structure.

## SYMMETRICAL GRYPTOSYSTEM

* As in symmetric algorithms it is impossible to use the complex mathematical transformations (that diminishes the fast action of the algorithm), in order to achieve such goals in the modern symmetric cryptography replacement and displacement operations are applied for with the multiple iterations.

## SYMMETRICAL GRYPTOSYSTEM

* Unfortunately, the block ciphers have significant fallback. That is their determined nature, which is expressed in the fact that the same text by means of the same keys is always transferred into the same cipher text. This fallback is tried to be suppressed by means of the encrypting regimes, in which the initialization vector is applied for, which enables to transfer the same text with the same keys into various cipher texts.

## TBC

* In 2002 the Article by M. Liskov, R. Rivest and D. Wagner was published, the idea stated in which that, initialization vector might be used not in the regime of encrypting, but in the algorithm itself. Such ciphers are called tweakable block ciphers.

## TBC

Tweakable block cipher overview

## HILL ALGORITHM

* In 1929 American mathematician Lester S.Hill by means of utilization of the linear algebra created $n$ gram encrypting algorithm, which enables to make one outgoing symbol of the ciphertext dependet onto the n number of the incoming symbols.

## MODIFIED HILL ALGORITHM

* In crypto algorithm 256 bits block is encrypted with the confidential keys. Upon entrance into the algorithm, the block to be encrypted shall be represented by means of the matrix, which is called the standing matrix, where each is the binary byte. Binary line to be encrypted shall be recorded in the matrix from the left to the right horizontally.

## MODIFIED HILL ALGORITHM

$$
\mathrm{M}=\left(\begin{array}{llll}
a_{11} & a_{12} & a_{13} & a_{14} \\
a_{21} & a_{22} & a_{23} & a_{24} \\
a_{31} & a_{32} & a_{33} & a_{34} \\
a_{41} & a_{42} & a_{43} & a_{44}
\end{array}\right)
$$

* All the operations, which are completed for the text to be encrypted into the algorithm, are completed on this matrix. We will deal with one operation only, which provides the open text structure effective covering into the ciphertext.

## MODIFIED HILL ALGORITHM

* This operation mathematically might be recorded quite simply: $M \times A(\bmod 256)$. Where $A$ is the matrix and that matrix shall by all means have the reverse matrix.

$$
\begin{aligned}
& \text { while(noSuccess) } \\
& \begin{array}{l}
\text { tryAgain(); } \\
\text { if(Dead) } \\
\}
\end{array} \quad \text { break; }
\end{aligned}
$$

## ENCRYPTION

* Let us suppose we have open text: If two wrongs don't make a right, try three. We take the starting 16 symbols, transform them into ASCII code and represent $4 \times 4$ dimensional A matrix:

| I | f | t | w | o | w | r | o |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 73 | 102 | 116 | 119 | 111 | 119 | 114 | 111 |
| $\mathbf{n}$ | g | s | d | o | n | ' | t |
| 110 | 103 | 115 | 100 | 111 | 110 | 96 | 116 |

## ENGRYPTION

| 73 | 102 | 116 | 119 |
| :---: | :---: | :---: | :---: |
| 111 | 119 | 114 | 111 |
| 110 | 103 | 115 | 100 |
| 111 | 110 | 96 | 116 |

Then we take the following 16 symbol, which we also transfer into ASCII code, represent them as $4 \times 4$ dimensional B matrix:

## ENGRYPTION

| m | a | k | e | a | r | i | g |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 109 | 97 | 107 | 101 | 97 | 114 | 105 | 103 |
| h | t | , | t | r | y | t | h |
| 104 | 116 | 44 | 116 | 114 | 121 | 116 | 104 |

| 109 | 97 | 107 | 101 |
| :---: | :---: | :---: | :---: |
| 97 | 114 | 105 | 103 |
| 104 | 116 | 44 | 116 |
| 114 | 121 | 116 | 104 |

## ENGRYPTION

- N and M matrix calculated by us in advance:

## ENGRYPTION

A matrix is multiplied for $N$ matrix, as the result of which $4 \times 4$ dimensional $A_{1}$ matrix is received again:

| 128 | -13 | 4 | 171 |
| :---: | :---: | :---: | :---: |
| 130 | -116 | -124 | 133 |
| 111 | -108 | -111 | 116 |
| 89 | -120 | -114 | 74 |

## ENGRYPTION

* The received $\mathrm{A}_{1}$ matrix is brought with 256 module and transferred into the binary system:

| 128 | 243 | 4 | 171 | 130 | 140 | 132 | 128 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 10000000 | 11110011 | 00000100 | 10101011 | 10000010 | 10001100 | 10000100 | 10000000 |
| 133 | 111 | 148 | 145 | 116 | 89 | 136 | 142 |
| 10000101 | 01101111 | 10010100 | 10010001 | 01110100 | 01011001 | 10001000 | 10001110 |

## ENGRYPTION

* With the analogue method we act at B matrix only instead of N matrix we use M matrix and result is:

125
165
159
137
90
123
121
73

0111110110100101100111111000100101011010011110110111100101001001

| 216 | 200 | 16 | 204 | 121 | 116 | 104 | 114 |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |

1101100011001000000100001100110001111001011101000110100001110010

## DECRYPTION

x Decryption is the reversed process of encryption with the insignificant differences. While encrypting instead of the applied N and M matrixes we use 256 module reversed $\mathrm{N}^{-1}$ and $\mathrm{M}^{-1}$ matrixes accordingly.
$\mathrm{N}^{-1}$ matrix:

| -1 | 2 | -2 | 2 |
| :---: | :---: | :---: | :---: |
| -2 | -1 | -2 | -2 |
| 1 | 1 | 1 | 2 |
| 1 | -1 | 2 | -1 |

## REGRYPTION

$\times \mathrm{M}^{-1}$ matrix:

$$
\begin{array}{cccc}
-2 & -1 & 2 & 2 \\
-2 & -2 & -1 & -2 \\
1 & 1 & 1 & 2 \\
2 & 1 & -1 & -1
\end{array}
$$

## CONCLUSIONS

* We have considered only a single operation, which provides the open text structure effective covering into the ciphertext. In our case 127 bits changed from 256 bits, which is good result.
The algorithm is currently under construction and will be available in the near future, the possibility of his performances.

## THANK YOU FOR YOUR ATTENTION
