The future for strong gravitational lensing

Thursday 17 December 2015 14:21 (21 minutes)

The Euclid mission is expected to discover perhaps two orders of magnitude more strong gravitational lenses than are known today. These will be quasar-galaxy, galaxy-galaxy and galaxy-cluster lenses. I will discuss what is required to find and process such a large number of lenses. I will then describe what can be learned from these lenses with respect to the dark matter distribution, cosmology and gravitational theory. In the process I will discuss new methods for analysing lensing data.
