The data acquisition system of the KM3NeT detector

S. Biagi1, T. Chiarusi2, P. Piattelli1, and D. Rea1 on behalf of the KM3NeT Collaboration

KM3NeT (KM-scale Neutrino Telescope) [1] is a future European research facility in the Mediterranean Sea which will house a neutrino telescope of cubic kilometer scale (Fig. 1). The Digital Optical Module (DOM) is a high pressure resistant glass vessel with 31 3" Photomultiplier Tubes (PMT) inside (Fig. 2). The PMTs collect the Cherenkov light produced by charged leptons and convert it into electronic signals [2]. 18 DOMs are arranged on string-like structures, the detection units, anchored on the sea bed and kept vertical by a buoyancy system. The detection units are connected with submarine junction boxes and through them to shore for power feed and data transmission. The all-data-to-shore data taking approach follows the choice done by ANTARES [3]. No trigger is done underwater; all signals from PMTs arrive onshore where they are triggered and processed by farm of computers. The Trigger and Data Acquisition System (TriDAS) must be able to handle an extremely large throughput of data arriving from off-shore; the DAQ modularity and scalability are needed properties.

The 31 PMTs are suspended in a foam support structure: 19 PMTs in the lower hemisphere and the remaining 12 in the upper hemisphere. Each PMT has its own adjustable high voltage supply integrated in the PMT Base. In order to translate these signals into the arrival time of the photons, they are processed by Time to Digital Converters (TDC) core embedded in the Field Programmable Gate Array (FPGA) of the Central Logic Board (CLB) [4]. The CLB integrates the White Rabbit Protocol [5], a fully deterministic Ethernet-based network for general purpose data transfer and synchronization, that allows to synchronize all the KM3NeT DOMs with 1 ns resolution. The data provided by the PMT Bases is collected and distributed to the CLB by means of two boards, the Octopus Boards. The CLB contains the electronic components for an optical link to shore. All necessary DC power is provided by the Power Board [6]. An aluminium structure provides heat conduction between the electronics inside and the exterior of the sphere. The electronic boards contained inside the DOM are shown in Fig. 3.

The ensemble of hardware infrastructures and software collections in charge of the data acquisition, aggregation, filtering and save-to-disk is called TriDAS (Trigger and Data Acquisition System, Fig. 4). All the TriDAS elements are connected within a local 10 Gbps network which comprises also the underwater detector. The first step of the data aggregation onshore is the DataFilter (DF), that distributes unfiltered data arriving from a sector of the detector to the computer farm that takes care of the online analysis of data from acoustic sensors for the positioning system; the optical DF is responsible of the online analysis of data from acoustic sensors for the positioning system; the optical DF is the software devoted to the trigger of PMT data. Each optical DF receives from all the active DQs a block of data related to a specific time window (the timeslice) with a typical length of 100 ms. The optical DF handles the data of the entire apparatus with respect to the assigned timeslice. The filtered data are finally sent to a DataWriter, that writes on disk a ROOT file [7]. Each acoustic DF receives all data arriving from a DQ in a continuous stream, calculates the sound arrival time produced by the underwater positioning system and sends the result to a DataBase. The ControlUnit, the user interface of the detector, coordinates all the operations of the TriDAS and operates the DOMs using a dedicated Slow Control protocol. The number of necessary DFs scales with the detector throughput and with the algorithms complexity without changing the DAQ design. The data reduction is more than a factor 100 with respect to the throughput from the detector.

About 120 Gbps throughput is expected from the full detector composed of 690 detection units, assuming a photon-hit rate of 6 kHz for each 3" PMT. The first detection unit of KM3NeT that uses all the technologies described here will be installed soon offshore the French coasts near Toulon [8].
