

# Emittance vs Intensity (~LHC beams)

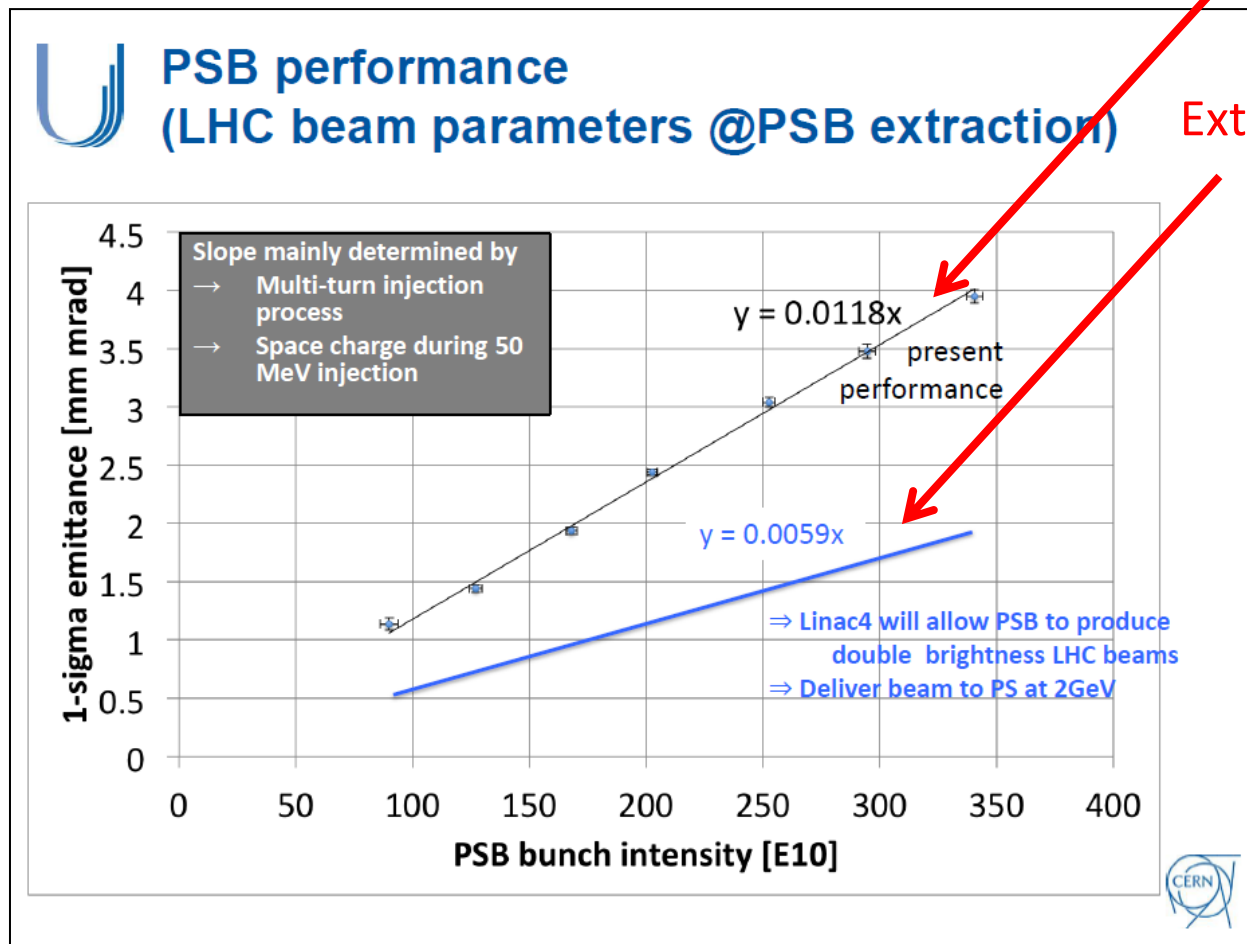

E. Benedetto

LIU injection meeting

13/10/2014

# Emittance vs. Intensity curve

- Simulate the curve with Linac4

# Simulations with PTC-Orbit

- Transversely MATCHED distribution (Gaussian) (\*)
  - With a given emittance
  - Scan on the Intensity
  - Scan on the working point
- Let it evolve for  $\sim 7$ ms, during the fall of the chicane bump
- **Quadrupolar** errors at the BSW + eddycurrents + Compensation QDE3, QDE14 (time varying)
  - Beta-beating (mostly in vertical)
  - Excitation of **half-integer**
  - Excitation of **the integer** line

Should be enough... (?)

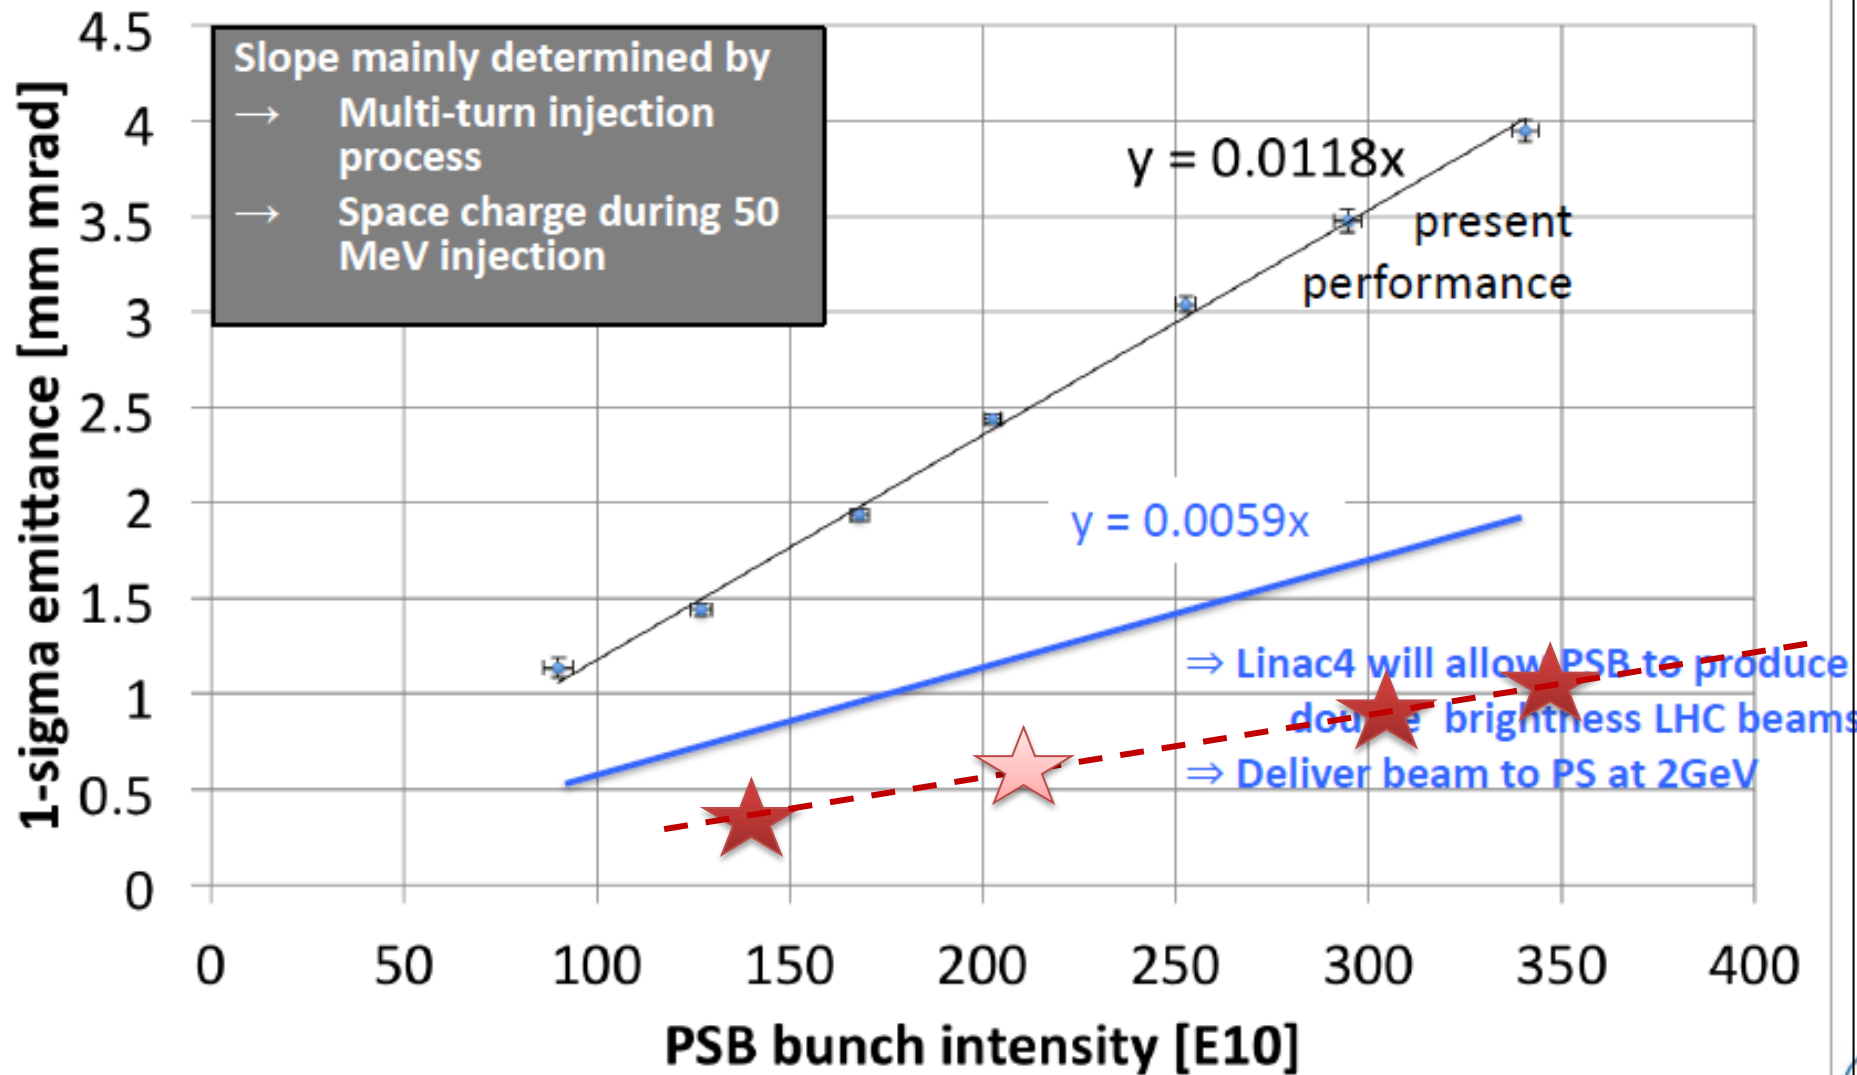

(\*) In longitudinal (for the time being): I let a “rectangular” distribution evolve in an accelerating bucket,  $h_1+h_2$ . NOT YET optimized...

# Emittance evolution

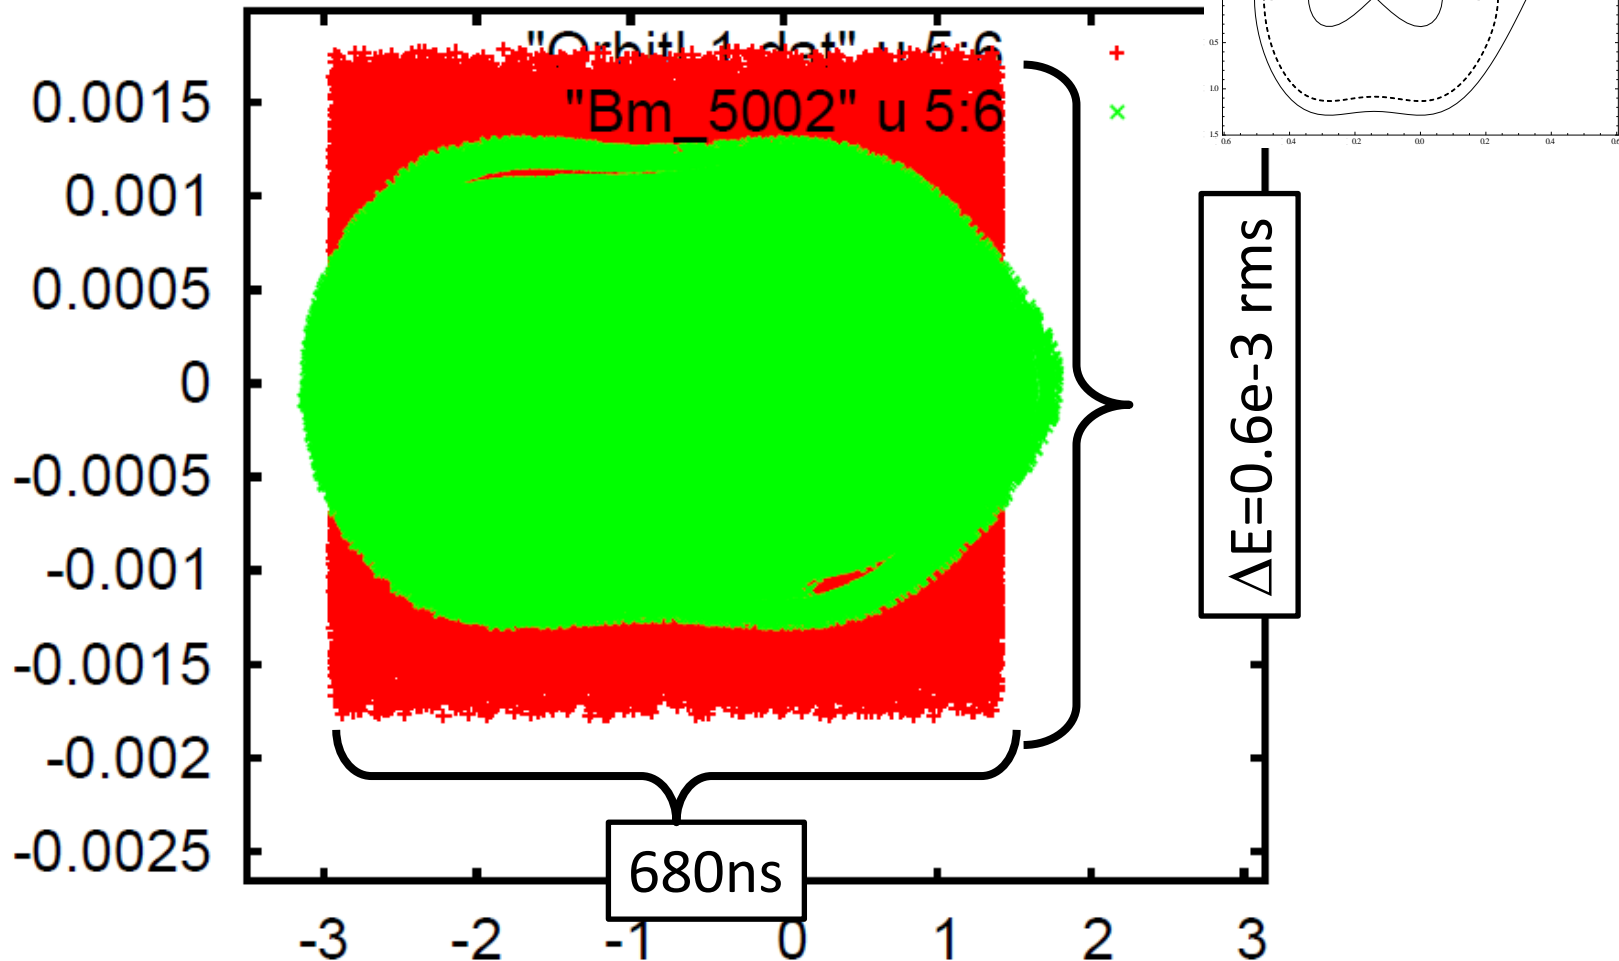

$$(E_x^* + E_y^*)/2$$

...Forgive me for the zoo of lines !!!

# Longitudinal emittance

# Summary

- First ~rough approach
- Assuming no specific L4 intensity, no painting, Gaussian beams.
- Longitudinal emittance should be computed!!!
- Scan on the working point:
  - Expect some gain in the H plane if going far from  $Q_x=4.0$
  - It should work since not a conventional MultiTurn inj (losses at septum!).

What does it happen if transverse painting @ different  $Q_x$ ?
