

# The HERAFitter project and results using HERAFitter

S. Glazov (DESY), for the HERAFitter developers' team

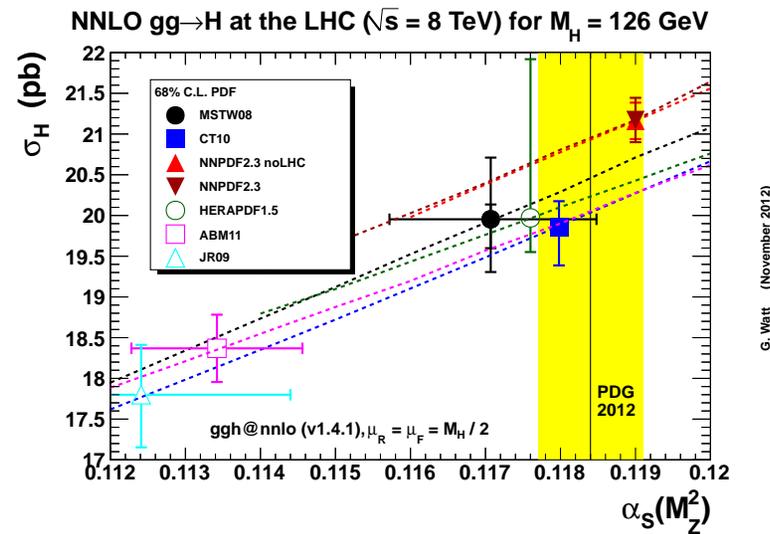

SM@LHC 2015, Florence.

# Cross sections at LHC and PDFs

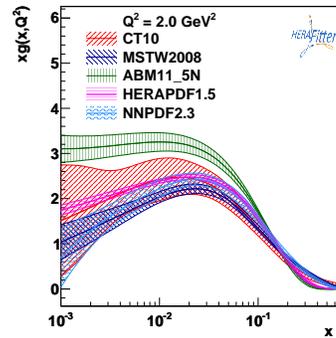

The cross sections are given by a convolution of the **parton distribution** and coefficient **functions**,  $\sim x_1 f_1(x_1, \mu) x_2 f_2(x_2, \mu) \hat{\sigma}(x_1, x_2, \mu)$ . PDFs are essential for predictions at the LHC.

# PDFs from different groups

- Many groups, [ABM](#), [MSTW](#) ( $\rightarrow$ MMHT), [CTEQ](#) ( $\rightarrow$ CT and CJ), [HERAPDF](#), [NNPDF](#), [JR](#), provide PDFs based on QCD analysis of DIS and  $pp$  data.
  - In some cases, results of these groups do not agree with each other within quoted uncertainties.
- $\rightarrow$  [HERAFitter](#) is an open source platform to include coefficient function codes from different groups, common ground for benchmarking.
- $\rightarrow$  [HERAFitter](#) is a tool to optimize experimental measurements to maximize their PDF sensitivity.

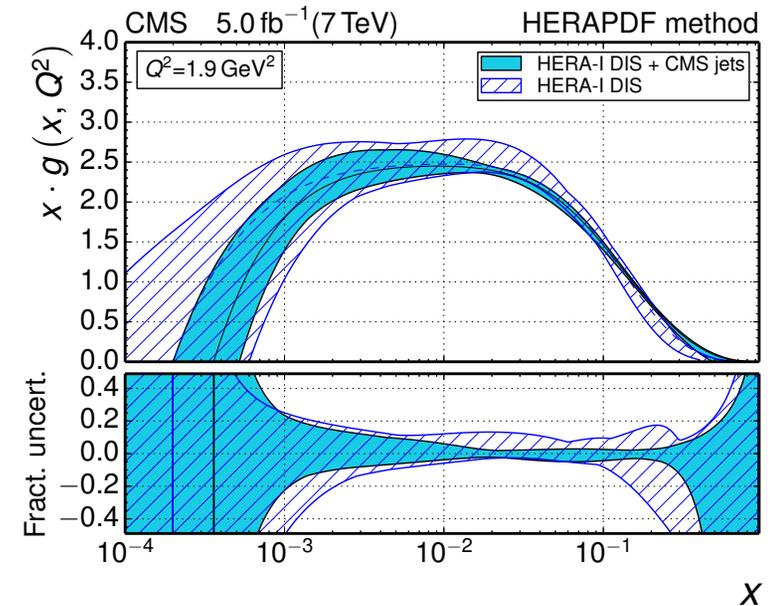

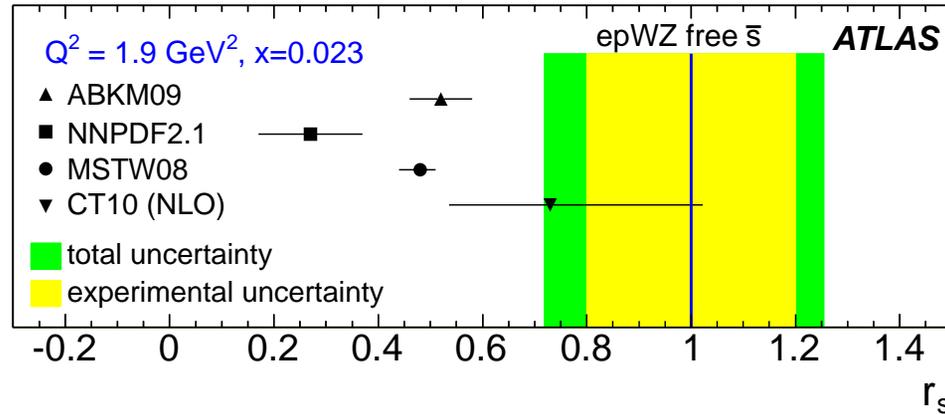

# HERAFitter in a nutshell

- Open-source program for development of QCD analyses [herafitter.org](http://herafitter.org)
- Fast LO, NLO and NNLO evolution code using the QCDNUM and APFEL programs.
- Coefficient functions for deep inelastic scattering processes using the fast convolution engine of QCDNUM and codes from ACOT, RT, ABM, FONLL. Coefficient functions for  $pp$  and  $p\bar{p}$  processes using APPLGRID and FastNLO programs.
- Alternative evolution: dipole model and TMD gluons.
- Flexible interface to include new data with correlated uncertainties.
- Fast analytic minimization vs nuisance parameters, MINUIT for PDFs.

arXiv:1410.4412

# Usage by LHC experiments

HERAFitter is used for a number of LHC publications and theory papers, e.g.

- Determination of the strange-sea distribution function suppression using ATLAS  $W, Z$  boson measurements ([PRL 109\(2012\) 012001](#)).
- PDF constraints and  $\alpha_S$  from the inclusive jet measurement by CMS ([arXiv:1410.6765](#)).

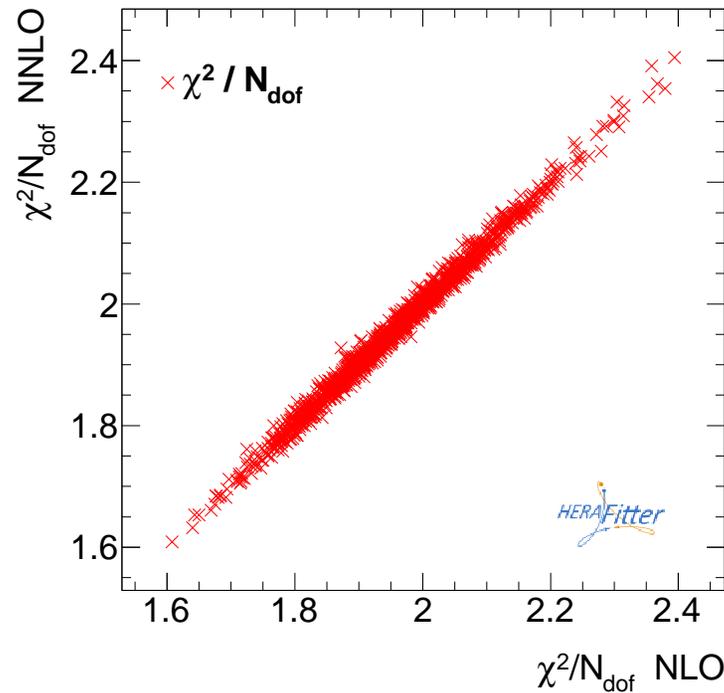

# LO, NLO, NNLO PDFs with correlated uncertainties

Consider two processes, for process 1 there are NLO and NNLO calculations, for process 2 only NLO calculations exist. How to minimize theory errors for the prediction of the cross-section ratio ?

- $\frac{\sigma_1^{\text{NLO}}(PDF^{\text{NLO}})}{\sigma_2^{\text{NLO}}(PDF^{\text{NLO}})}$  — use NLO coefficient functions and PDFs for both processes. Good if scale dependence is identical (e.g.  $W$  charge asymmetry). Large scale uncertainties otherwise.
- $\frac{\sigma_1^{\text{NNLO}}(PDF^{\text{NNLO}})}{\sigma_2^{\text{NLO}}(PDF^{\text{NLO}})}$  — use NNLO (NLO) coefficient functions and different PDFs for the first (second) process. Reduces scale uncertainties, however PDF uncertainties are not treated correctly (correlation information lost).
- $\frac{\sigma_1^{\text{NNLO}}(PDF^{\text{NNLO}})}{\sigma_2^{\text{NLO}}(PDF^{\text{NNLO}})}$  — use NNLO (NLO) coefficient functions for the first (second) process and common NNLO PDF. Reduces scale uncertainties, however PDFs are treated inconsistently for process 2 calculation.

→ need for PDF sets with correlated uncertainties between different orders.

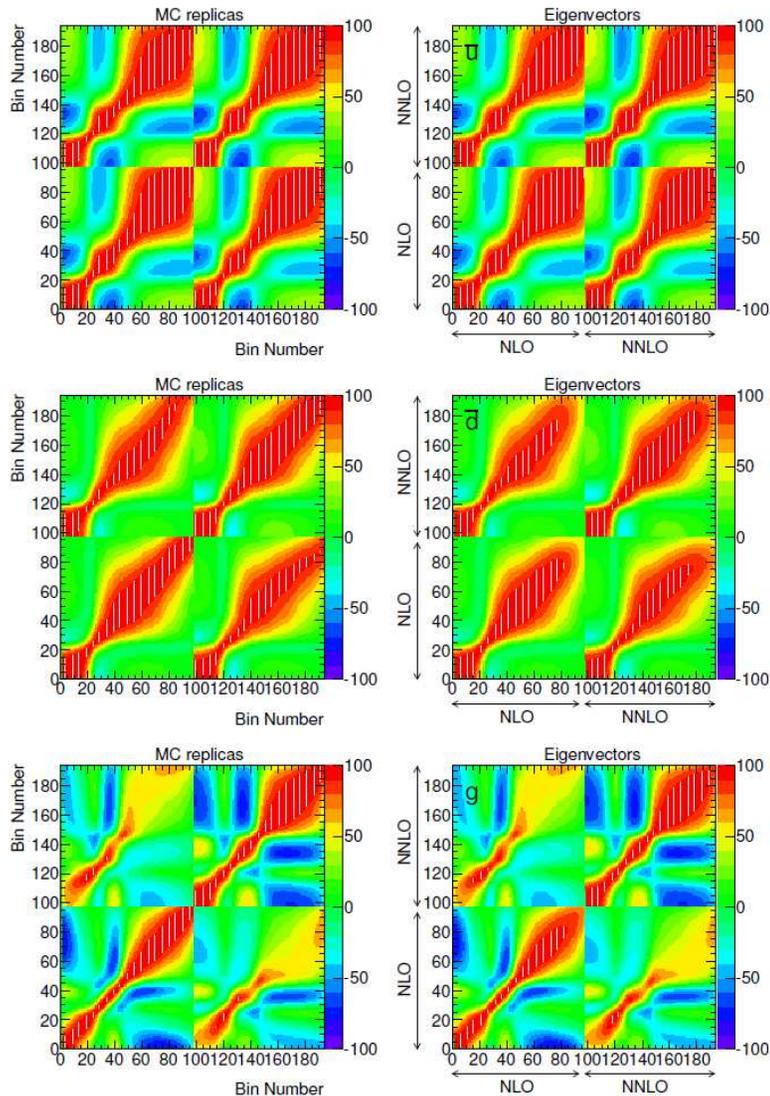

# Correlated analysis methodology

- Fit using HERA data only, similar to HERAPDF1.0.
- Synchronize QCD fit settings for fits at different orders (parameterisation, starting scale, data cuts)
- Use MC method for uncertainties, synchronize seeds for fits at different orders.

**arXiv:1404.4234**

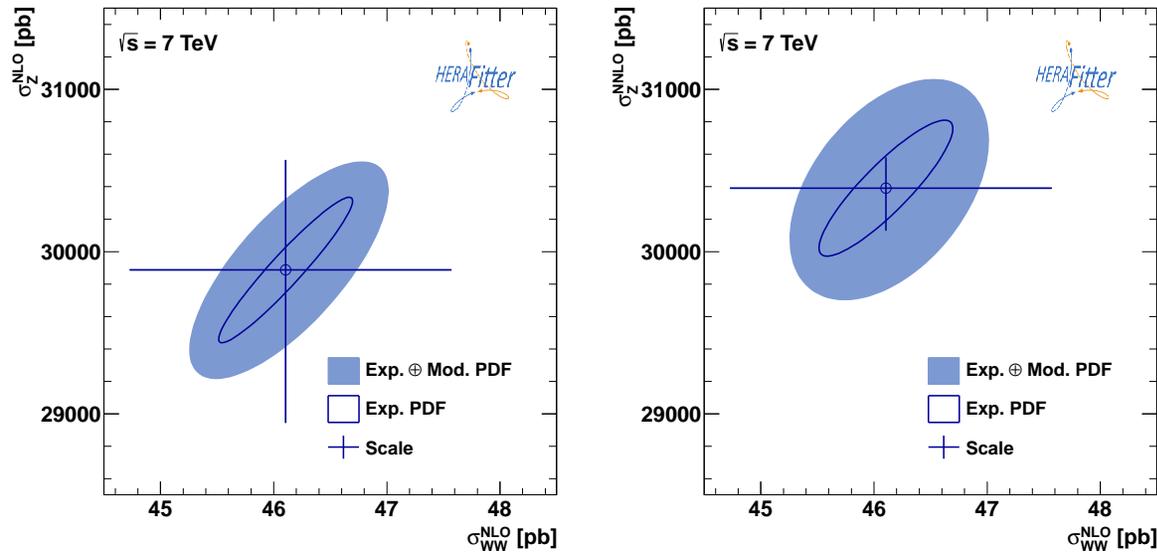

# Correlated PDFs

(Bin number:  $\sim x$ )

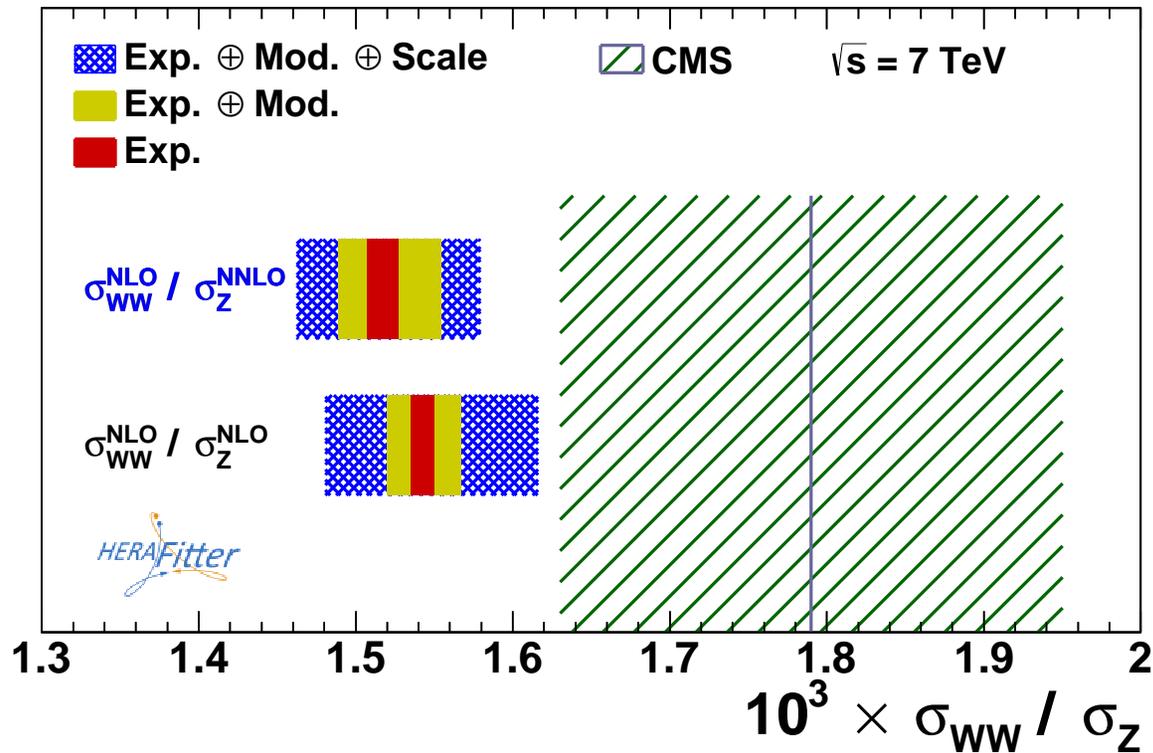

- PDF uncertainties determined by MC method are also transformed to eigenvector representation. This is achieved by diagonalization NLO-NNLO covariance matrix of PDF values at the QCDNUM  $x$ -grid points at the evolution starting scale  $Q^2 = 1.7 \text{ GeV}^2$  (fragments of the correlation matrix are shown here).
- High correlations for PDFs at similar  $x$  values. Very good description of the correlations using eigenvector representation. All PDFs except gluon at high  $x$  show high correlations between NLO and NNLO.

# Z and WW production at LHC

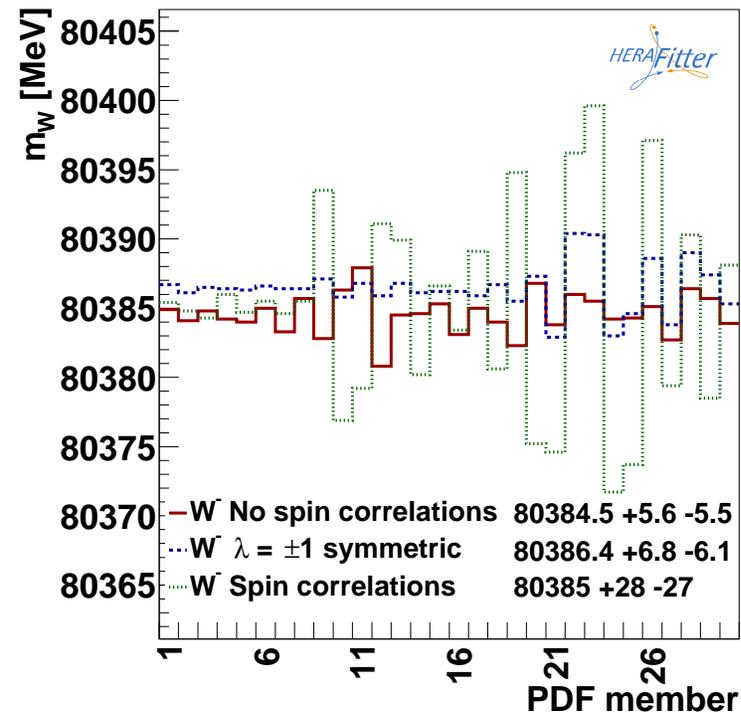

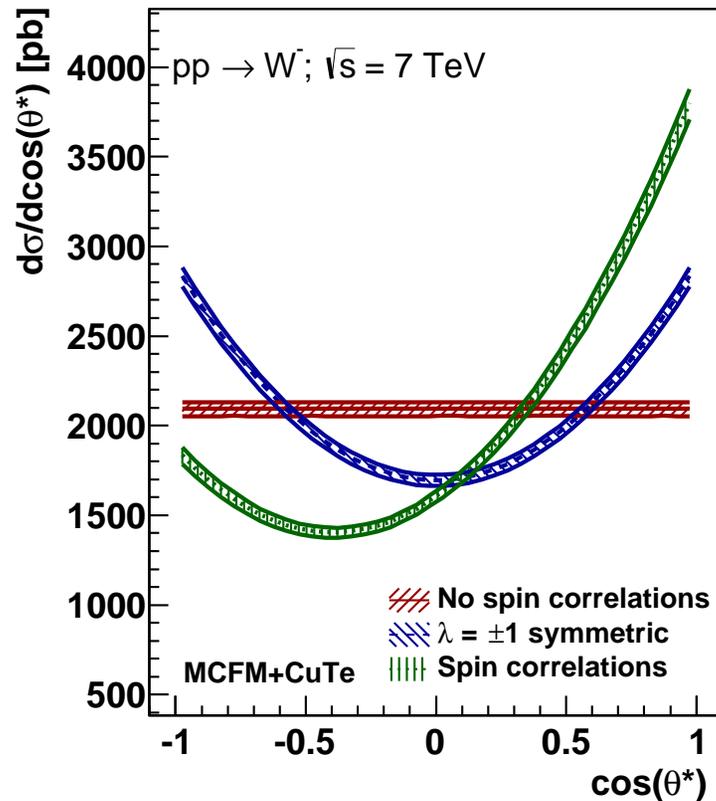

- Use case:  $Z$  boson and  $WW$  diboson production at the LHC.
- $Z$  boson cross section calculated using FEWZ at NLO and NNLO;  $WW$  diboson cross section calculated using MCFM at NLO.
- Similar PDF dependence leads to high correlation of PDF uncertainties. The correlation is reduced when using NNLO calculation for  $\sigma_Z$ .
- Scale uncertainty is reduced when using  $\sigma_Z^{\text{NNLO}}$ .

# WW/Z cross-section ratio

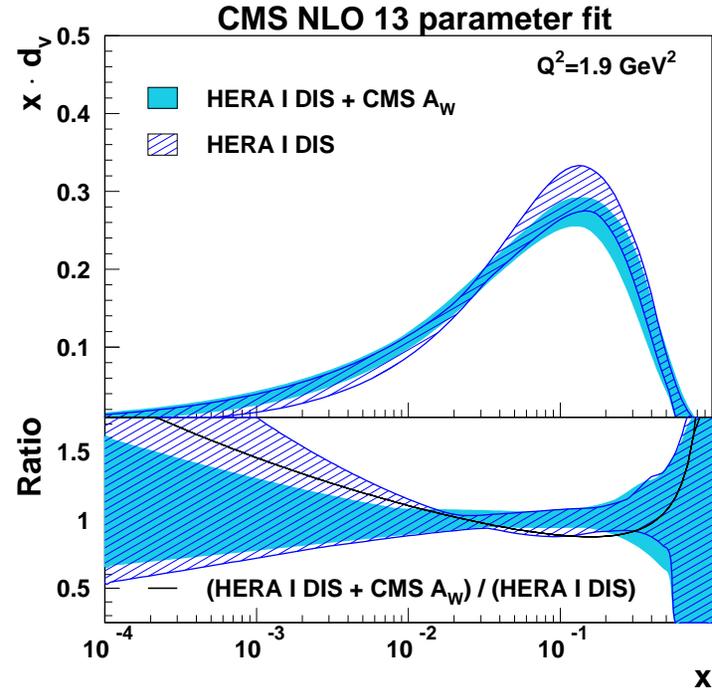

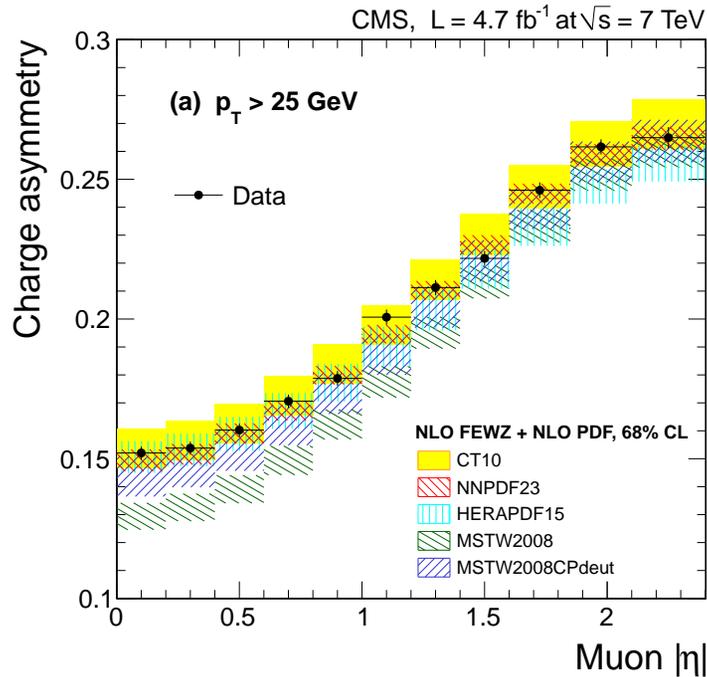

- Compare the ratio of  $WW$  to  $Z$  production cross sections to the measurement by the CMS collaboration ([EPJC73 \(2013\) 2610](#))
- While PDF uncertainty increases when using mixed NNLO-NLO predictions, the total uncertainty is reduced due to reduction of the scale uncertainty for the  $\sigma_Z$  prediction.

# $W$ mass measurement and PDF uncertainties

- At the LHC, the  $W$  boson mass can be measured using lepton  $p_T$ .
- $W$  boson is produced polarised; polarisation affects lepton kinematics.
- Effect of the polarisation can be studied by turning it off, completely or transverse polarisation only. Uncertainty in transverse polarisation, arising from **valence quarks**, has significant impact on the  $W$  mass.

# W asymmetry at the LHC

- Lepton charge asymmetry measurements from  $W^\pm \rightarrow \ell^\pm \nu$  decays,

$$A_\ell = \frac{\sigma_{W^+ \rightarrow \ell^+ \nu} - \sigma_{W^- \rightarrow \ell^- \nu}}{\sigma_{W^+ \rightarrow \ell^+ \nu} + \sigma_{W^- \rightarrow \ell^- \nu}},$$

at the LHC are sensitive to  $u_v - d_v$  densities.

- QCD analysis of the HERA+CMS asymmetry data illustrates reduction of the  $d_v$  uncertainty in the range where data contributes.

arXiv:1312.6283

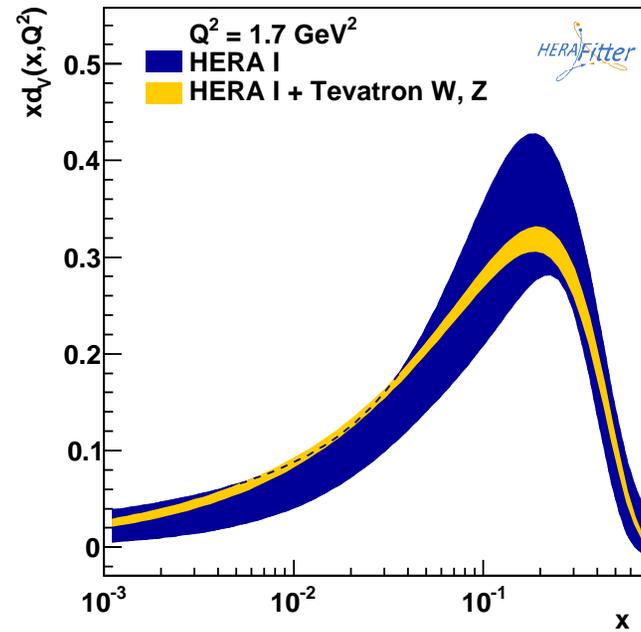

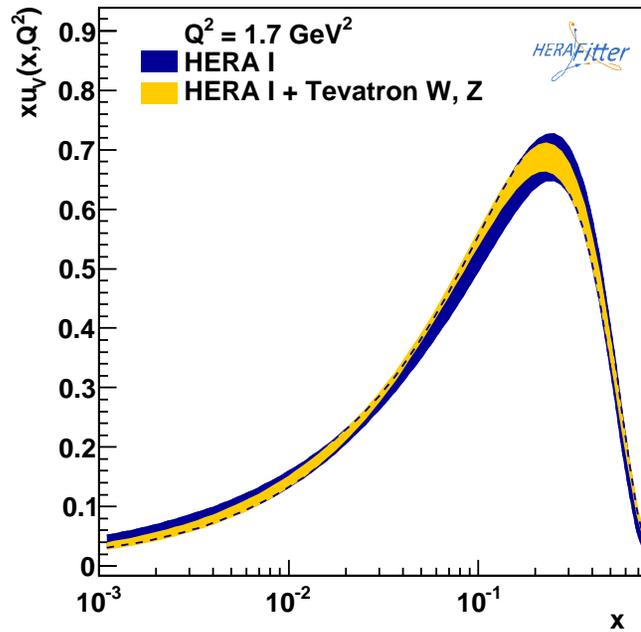

## Tevatron $W, Z$ production data

| Observable               | Experiment | Integrated luminosity | Kinematic requirements                               | Used in the nominal fit |
|--------------------------|------------|-----------------------|--|-------------------------|
| $d\sigma(Z)/dy$          | D0         | $0.4 \text{ fb}^{-1}$ | $71 < m_{ee} < 111 \text{ GeV}$                      | yes                     |
| $d\sigma(Z)/dy$          | CDF        | $2.1 \text{ fb}^{-1}$ | $66 < m_{ee} < 116 \text{ GeV}$                      | yes                     |
| $A_\mu$                  | D0         | $7.3 \text{ fb}^{-1}$ | $p_T^\mu > 25 \text{ GeV}, p_T^\nu > 25 \text{ GeV}$ | yes                     |
| $A_{W \rightarrow e\nu}$ | CDF        | $1.0 \text{ fb}^{-1}$ | none   | yes                     |
| $A_{W \rightarrow e\nu}$ | D0         | $9.7 \text{ fb}^{-1}$ | $E_T^e > 25 \text{ GeV}, p_T^\nu > 25 \text{ GeV}$   | yes                     |
| $A_e$                    | D0         | $9.7 \text{ fb}^{-1}$ | $E_T^e > 25 \text{ GeV}, p_T^\nu > 25 \text{ GeV}$   | <b>no</b>               |

- CDF and D0 experiments at Tevatron report measurements of  $d\sigma(Z)/dy$ , lepton ( $A_\ell$ ) and  $W$  ( $A_{W \rightarrow \ell\nu}$ ) charge asymmetry.
- At  $p\bar{p}$ ,  $d\sigma(Z)/dy$  is more sensitive to  $d$ -quark vs DIS,  $W$  and lepton charge asymmetries are sensitive to  $d_v$  and  $u_v$ -quark distributions.

Tevatron: [arXiv:0702025](https://arxiv.org/abs/0702025), [arXiv:0908.3914](https://arxiv.org/abs/0908.3914), [arXiv:1309.2591](https://arxiv.org/abs/1309.2591), [arXiv:0901.2169](https://arxiv.org/abs/0901.2169), [arXiv:1312.2895](https://arxiv.org/abs/1312.2895),  
[arXiv:1412.2862](https://arxiv.org/abs/1412.2862) HERAFitter: [arXiv:1503.05221](https://arxiv.org/abs/1503.05221)

# Impact of Tevatron data on $d_v$

- Study impact of Tevatron data by comparing fits to HERA-I data alone vs HERA-I plus Tevatron data.
- Perform parameterisation scan, starting from **basic form** and adding **exponential or polynomial** terms:

$$xf(x) = Ax^B(1-x)^C(1+Dx+Ex^2)\exp Fx$$

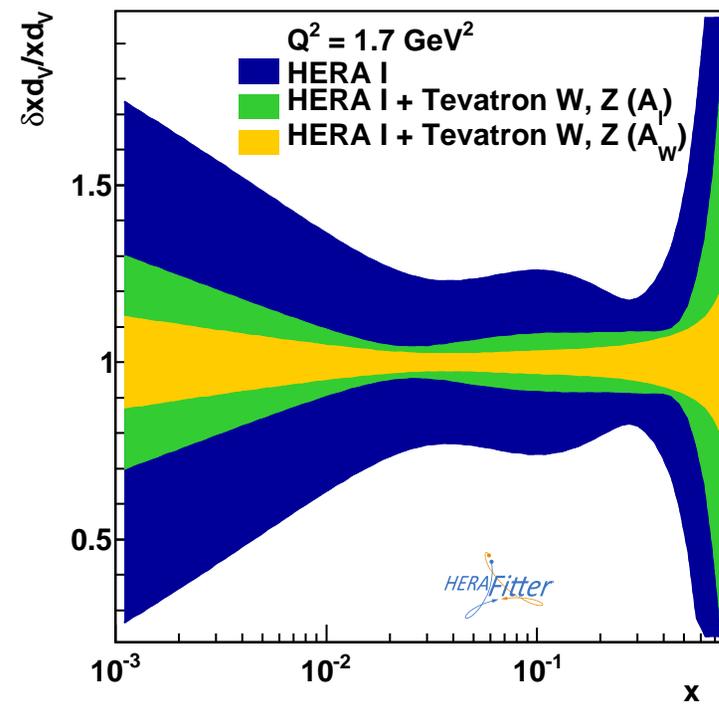

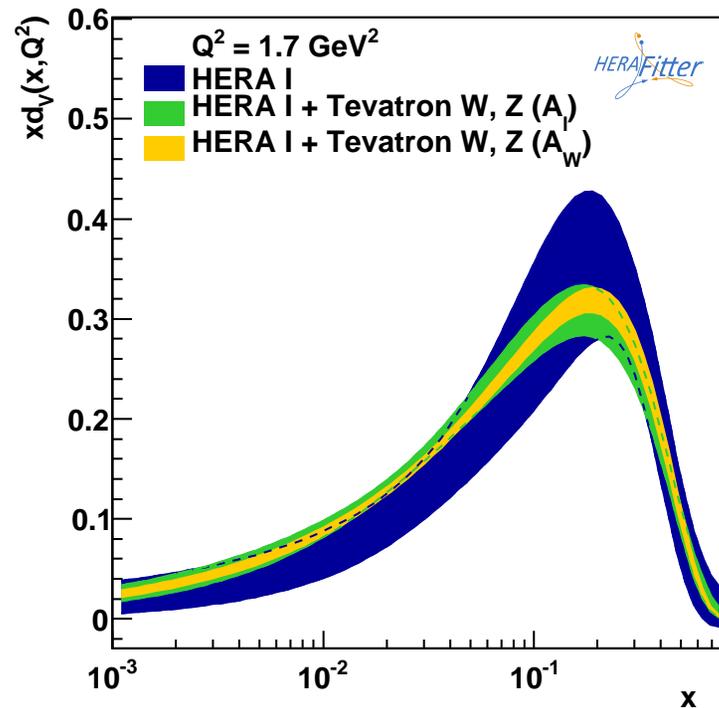

- Tevatron data have large impact on  $d_v$  uncertainty. After inclusion, relative uncertainties on  $d_v$  and  $u_v$  are about equal.

## Fit quality

| Data set                                 | (partial) $\chi^2/dof$ | partial $\chi^2/dof$ vs PDF set |        |          |
|--|------------------------|---------------------------------|--------|----------|
|  |                        | CT10                            | MMHT14 | NNPDF3.0 |
| D0 $d\sigma(Z)/dy$                       | 23 / 28                | —                               | —      | —        |
| CDF $d\sigma(Z)/dy$                      | 32 / 28                | —                               | —      | —        |
| D0 $A_\mu$                               | 12 / 10                | 13/10                           | —      | 12/10    |
| CDF $A_{W \rightarrow e\nu}$             | 14 / 13                | 14/13                           | —      | 15/13    |
| D0 $A_{W \rightarrow e\nu}$              | 8 / 14                 | 8/14                            | 5/14   | 2/14     |
| Total $\chi^2_{\min}$ (incl. HERA) / dof | 606 / 628              | —                               | —      | —        |

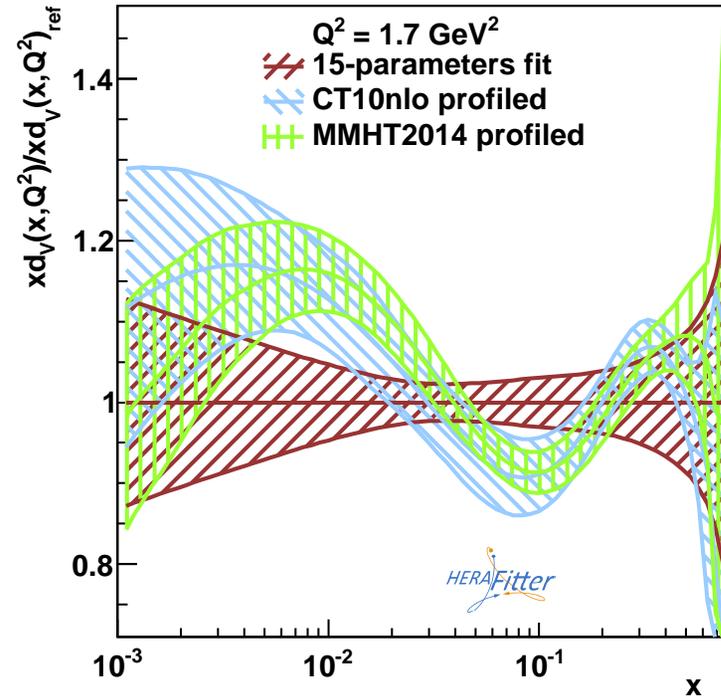

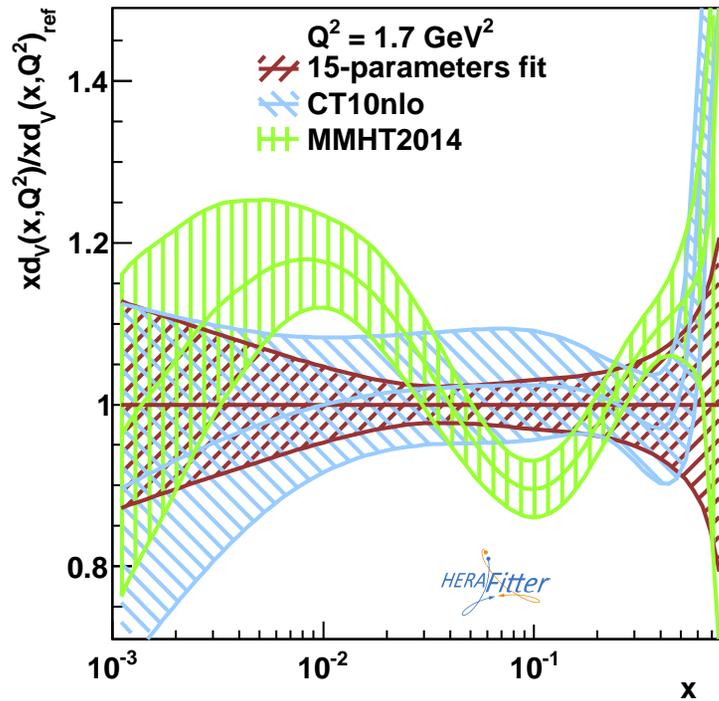

- All data sets can be described by the fit and predictions based on CT10, MMHT14 and NNPDF3.0 PDF sets with good quality.
- Both D0 and CDF data sets have comparable description: no tensions among Tevatron data.

# Fits to $W$ vs lepton asymmetry

- D0 provides asymmetry measurement in terms of lepton and  $W$  asymmetry. The later requires assumptions on the neutrino longitudinal direction.
- Fits to either data type are compatible,  $W$ -asymmetry data lead to more accurate PDFs.

# Impact on global PDFs

- Impact on PDFs can be studied by minimizing data to theory  $\chi^2$  vs nuisance parameters corresponding to PDF eigenvectors (“profiling”):

$$\chi^2(\beta_j^{\text{PDF}}) = C^T (D - T(\beta_j^{\text{PDF}})) C + \sum_j (\beta_j^{\text{PDF}})^2$$

- Uncertainties on  $d_v$  are reduced, CT10 and MMHT14 agree better.

## Summary

- HERAFitter is an open-source platform for QCD analyses.
- HERAFitter provides state-of-the-art calculations for LO,NLO,NNLO predictions and fast minimization tools.
- HERAFitter is actively used by the LHC experiments and theory community.
- Studies by HERAFitter developers of the correlated PDFs for different orders allows to reduce theoretical uncertainties for cross-section ratios, calculated at different order.
- Fits and profiling studies of the recent Tevatron  $W, Z$  data show importance of them to constrain  $d_v$  distribution, which is essential for the  $W$ -boson mass measurement at the LHC.

# PDF uncertainties for $Z$ and $WW$ production

**Table 2** Shifts of the  $WW$  di-boson and  $Z$  boson production cross sections due to the model and parameterisation variations in the PDF fit.

While experimental PDF uncertainties are all very highly correlated, uncertainties related to model and parameterisation assumptions show anticorrelation for some sources:

- Charm- ( $M_C$ ), bottom- ( $M_B$ ) quark mass parameters, strong coupling ( $\alpha_S(M_Z)$ ) and evolution starting scale ( $Q_0^2$ ) variations cause correlated variations of the cross sections.
- $r_s = \bar{s}/\bar{d}$  variation is anticorrelated between  $Z$  and  $WW$ .
- Requirement on input data scale ( $Q_{\min}^2$ ) is anticorrelated between NLO and NNLO.
