

Advanced Instrumentation Techniques at SNOLAB

Nigel Smith
SNOLAB

- The SNOLAB science programme requires advanced instrumentation to search for rare interactions and weak processes
 - Will focus on dark matter detector systems
- Challenges include
 - Minimal radiation backgrounds in detectors
 - High efficiency detection (single photon/phonon)
 - Particle discrimination (esp. neutrons and alphas)
- Techniques developed include
 - High light yield liquid noble gas
 - Low threshold solid state
 - Low threshold bubble chamber
- Common requirements for the programme include
 - Low radiological background assay capabilities (Ian Lawson)
 - Low radiological background environments (Chris Jillings)

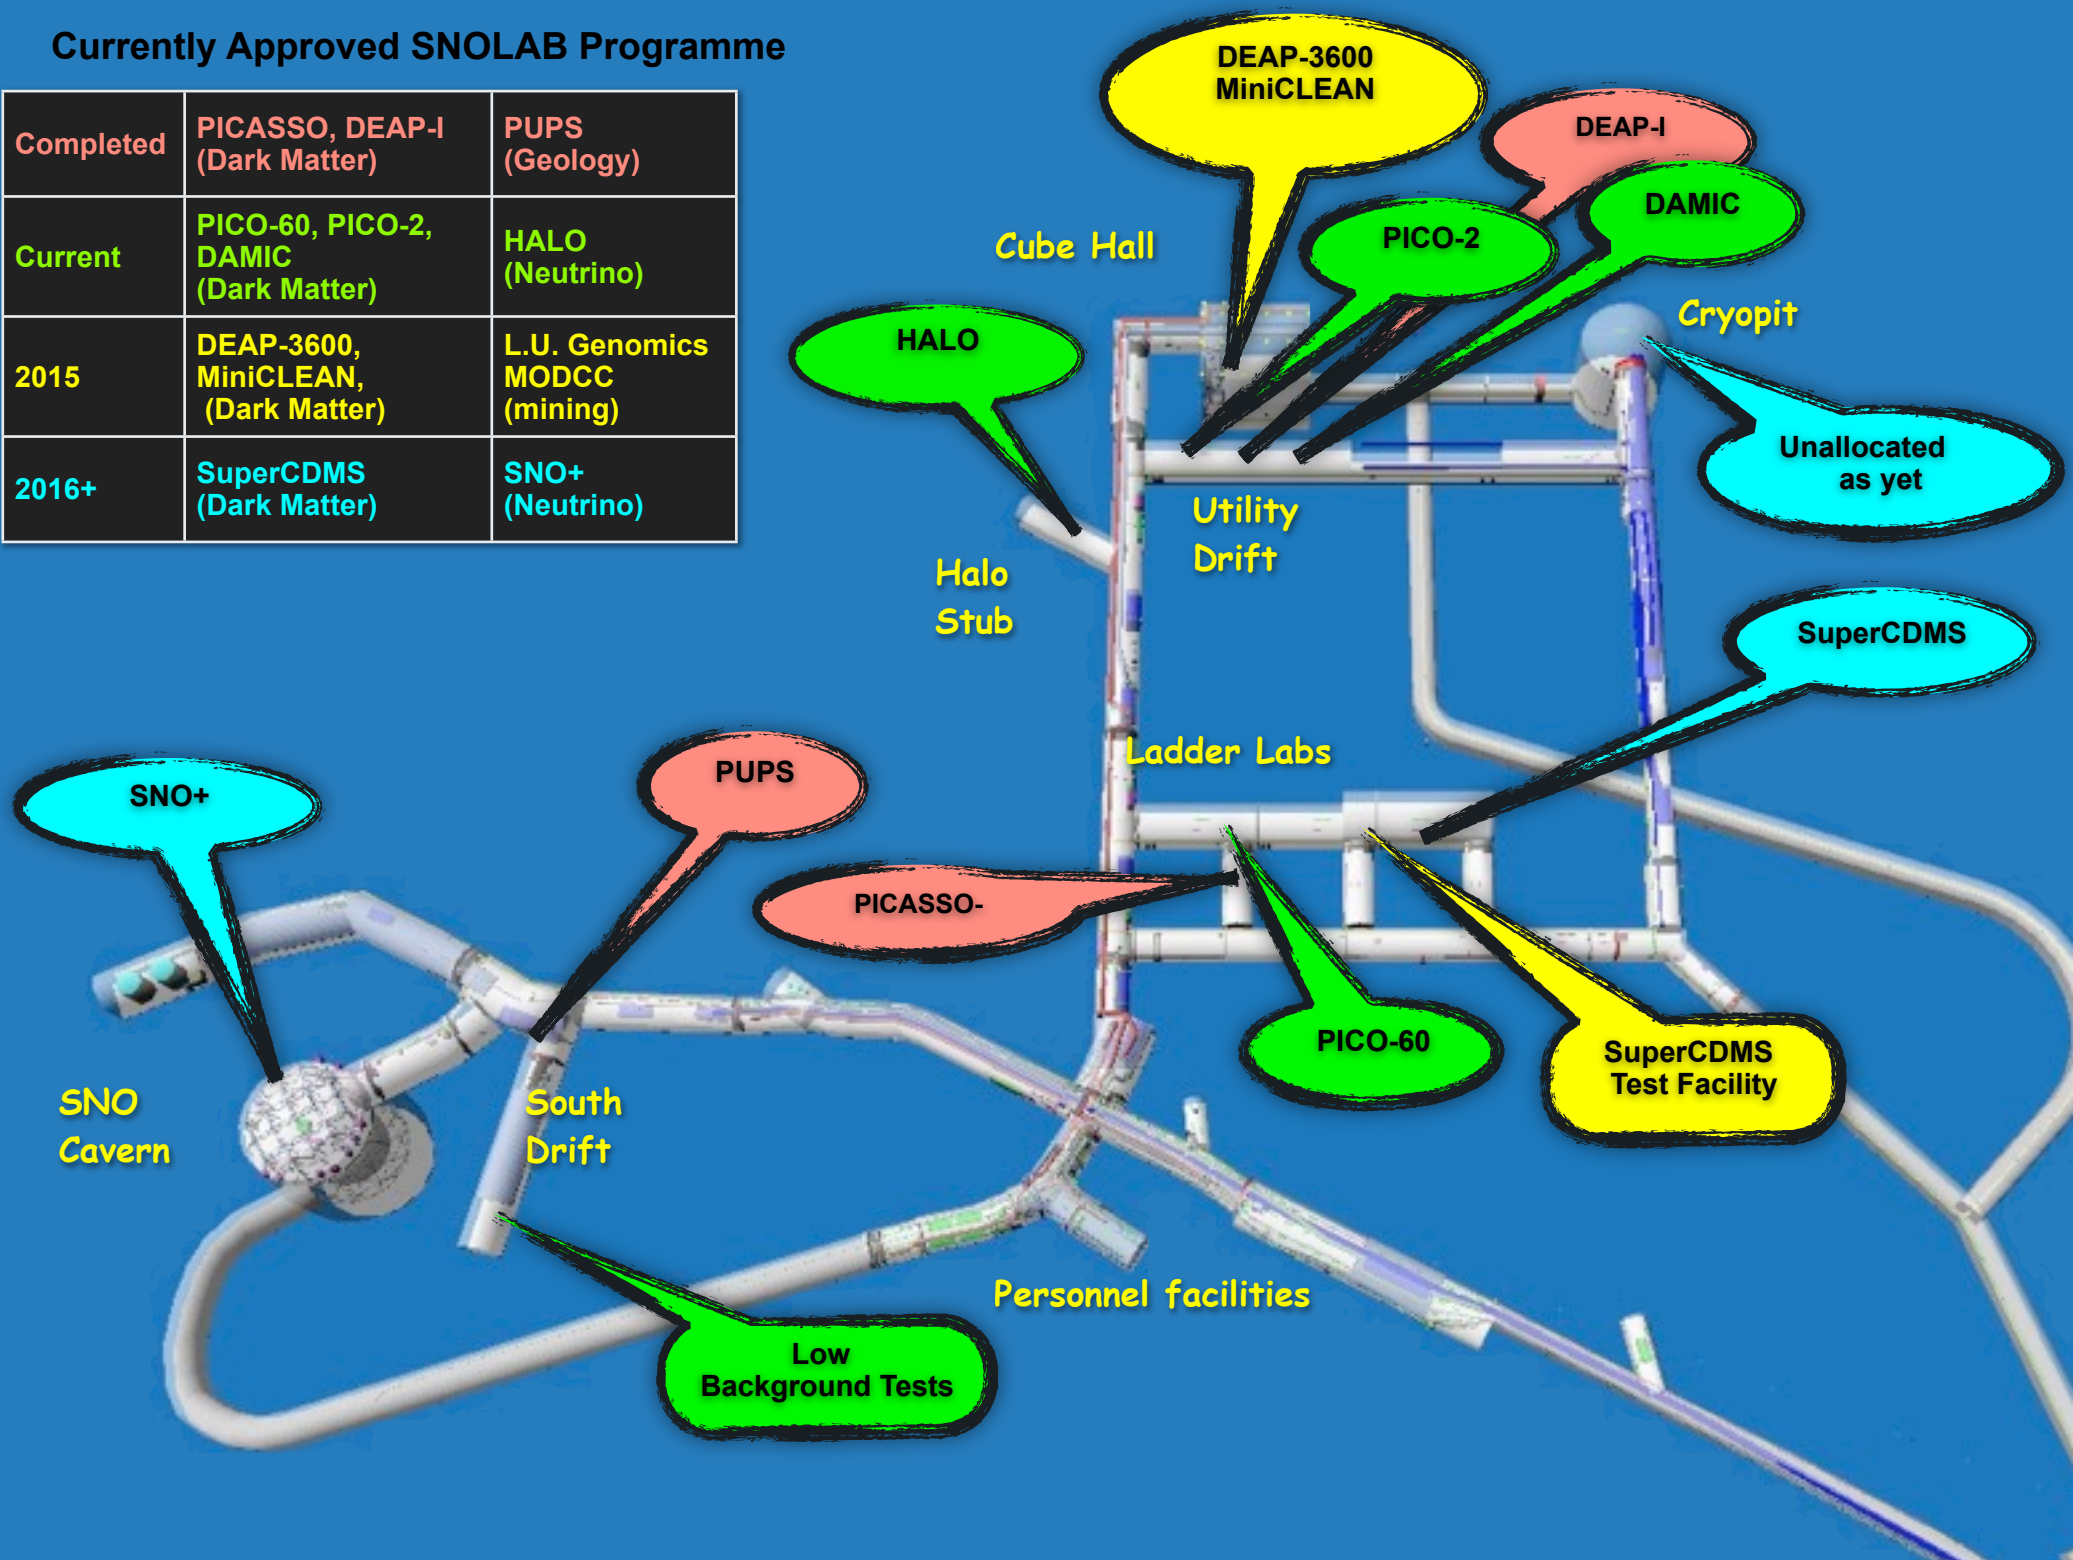

SNOLAB Science programme

Experiment	Neutrino	Dark Matter	Other	Space allocated	Status
CEMI			Mining Data Centre	Surface Facility	In Construction
COUPP-4		√		"J"-Drift	Completed
DAMIC		√		"J"-Drift	Operational
DEAP-1		√		"J"-Drift	Completed
DEAP-3600		√		Cube Hall	In Construction
DEAP-50T/CLEAN		√		Cube Hall	Letter of Intent
DMTPC		√		Ladder Labs	Letter of Intent
Ge-1T	√			Cryopit	Letter of Intent
nEXO	√			Cryopit	Concept Phase
HALO	√			Halo Stub	Operational
MiniCLEAN		√		Cube Hall	In Construction
NEWS		√		Cryopit?	Letter of Intent
PICASSO-III		√		Ladders Labs	Completed
PICO-2L		√		"J"-Drift	Operational
PICO-60		√		Ladder Labs	Operational
PICO-250		√		Ladder Labs	Letter of Intent
PINGU			Test facility	Ladder Labs	Letter of Intent
PUPS			Seismicity	Various	Completed
SNO+	√			SNO Cavern	In Construction
SuperCDMS		√		Ladder Labs	In Preparation
U-Laurentian			Genomics	External Drifts	Operational

Currently Approved SNOLAB Programme

Completed	PICASSO, DEAP-I (Dark Matter)	PUPS (Geology)
Current	PICO-60, PICO-2, DAMIC (Dark Matter)	HALO (Neutrino)
2015	DEAP-3600, MiniCLEAN, (Dark Matter)	L.U. Genomics MODCC (mining)
2016+	SuperCDMS (Dark Matter)	SNO+ (Neutrino)

Ways to search for Dark Matter

- Complementary techniques

Scattering

Annihilation

Production

$\tilde{\chi}$

$\tilde{\chi}$

f, q

f, q

The diagram illustrates three primary methods for dark matter detection: scattering, annihilation, and production. A central shaded circle represents the interaction point. A red arrow labeled 'Scattering' points from a dark matter particle $\tilde{\chi}$ on the left to another $\tilde{\chi}$ on the right. Two red arrows labeled 'Annihilation' and 'Production' point downwards and upwards respectively, both leading to the labels f, q , representing standard model particles.

The challenges for direct searches

- WIMP nuclear recoil signal is:
 - **Low rate** (0.1 - 10^{-5} events/kg/day)
 - **Small energy** (1-100 keV actual: observed is less)
 - Similar observed exponential spectrum to many background signals (PMT, γ , etc.)
- Detection technique must be:
 - **Low background**
 - Gamma, beta: from U/Th/Co/Pb/etc radio-impurities
 - Neutron: from U/Th radio-impurities and c.r. μ spallation
 - **Low threshold**
 - To minimise form factor, maximise spectrum
 - **Discriminating** - Position sensitivity
 - Difference between WIMPs/n and γ/β , background rejection, directionality
 - **Large massive**

- Noble Liquids: DEAP-I, MiniCLEAN, & DEAP-3600
 - Single Phase Liquid Argon using pulse shape discrimination
 - High light yield detection required: single photon counting
 - Will measure Spin Independent cross-section.
- Superheated Liquid / Bubble chamber: PICASSO, COUPP => PICO
 - Superheated droplet detectors and bubble chambers.
 - Insensitive to MIPS radioactive background at operating temperature, threshold devices;
 - Requires strong alpha particle discrimination;
 - Measure Spin Dependent cross-section primarily, COUPP has SI sensitivity on iodine;
- Solid State: DAMIC, SuperCDMS
 - State of the art CCD (DAMIC) Si / Ge crystals with ionisation / phonon readout (SuperCDMS).
 - Low threshold devices, high efficiency
 - Mostly sensitive to Spin Independent cross-section.

(Liquid) Noble Gas detectors

Gas	Single phase	Double phase
Xenon	ZEPLIN I, XMASS	ZEPLIN, XENON, LUX
Argon	DEAP, CLEAN	DarkSide, ArDM
Neon	CLEAN	-

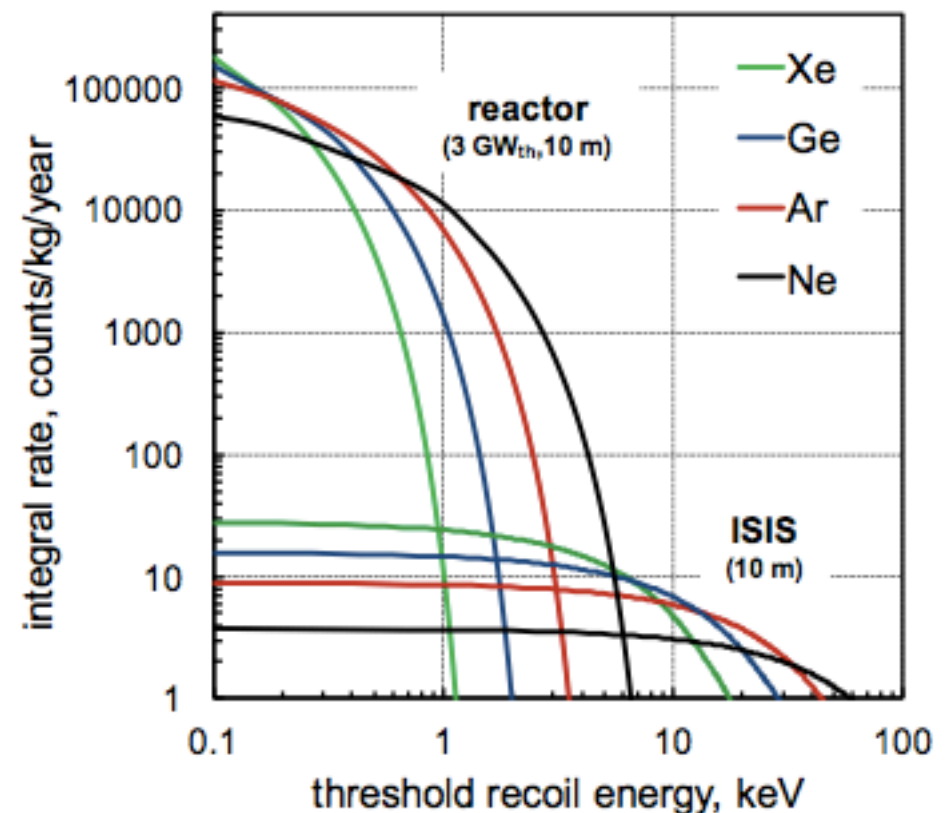

- Single phase - scintillation
 - recombination occurs
 - singlet/triplet ratio 10:1 nuclear:electron
- Double phase - ionisation/scintillation
 - measure ionisation directly (through electroluminescence)

Response to elastic scattering

- Principle technique for WIMPs and neutrino detection is coherent elastic scattering off target nuclei
- For WIMP detection
 - low threshold required in xenon to maximise signal
 - higher threshold in argon for discrimination

Chepel/Araújo

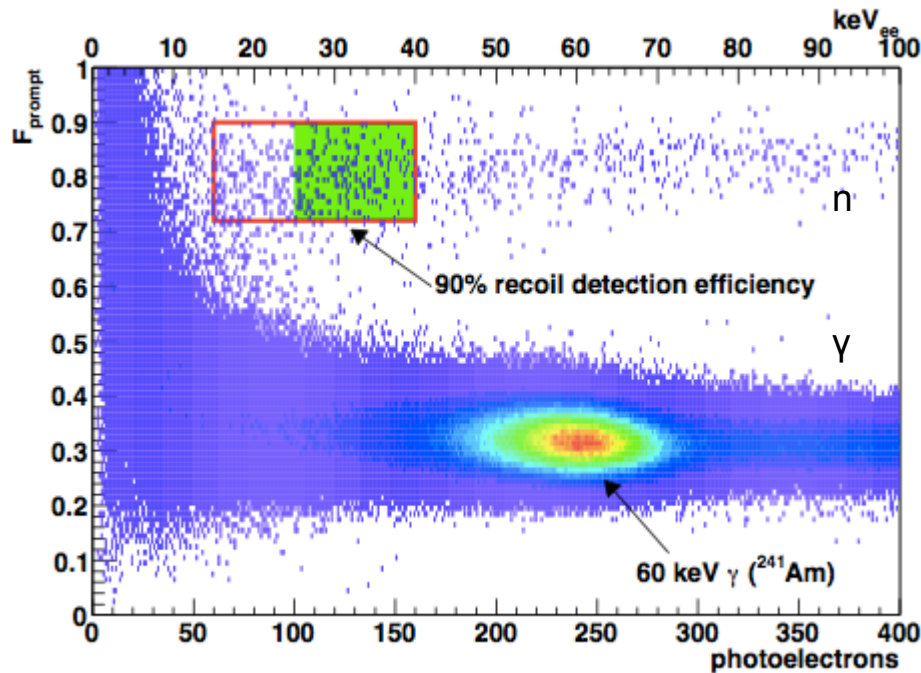

Particle identification

- Discrimination between nuclear and electron recoils
- Single phase detectors use pulse shape discrimination
- Double phase use ratio ionisation to scintillation (+PSD for LAr)

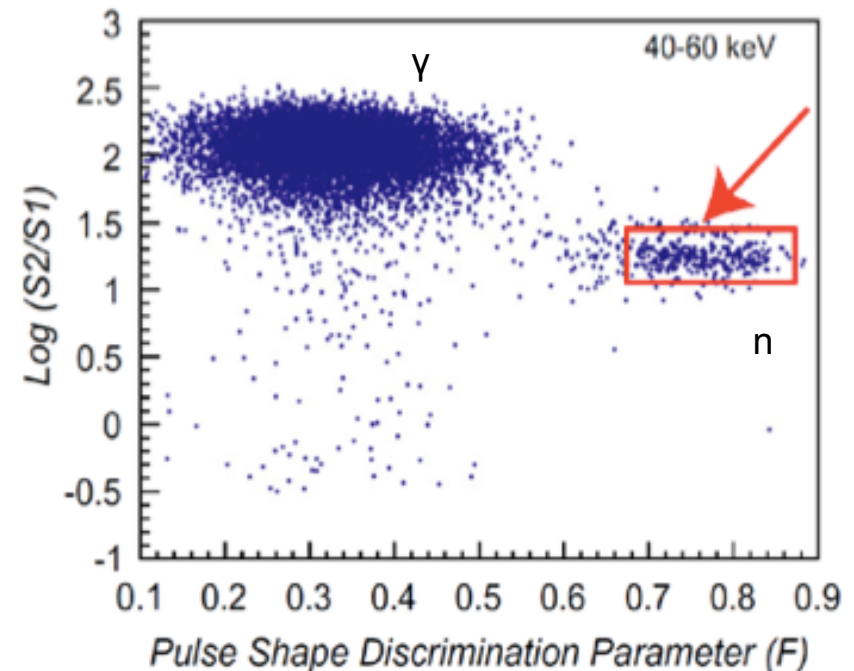

ZEPLIN-III - LXe

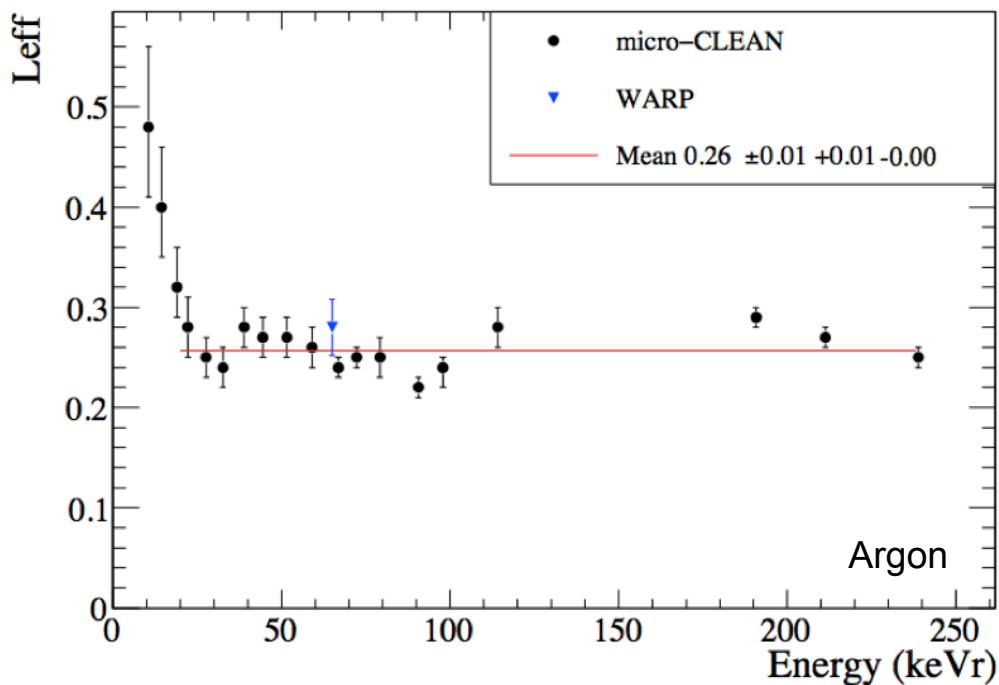

DEAP - LAr

WARP - LAr

- Relative scintillation yield measures quenching of scintillation in nuclear recoils compared to electron recoils
 - measured directly through dedicated mono-energetic neutron beam scattering tests, compared to gamma rays
 - also extracted from poly-energetic neutron source calibrations, compared to simulations

Properties of Noble Gas detectors

- Large mass targets possible
- Re-purification of target possible
- Fiducialisation against surface backgrounds
- High primary scintillation yield (40 photons/keV)
 - transparent to own light
- High ionisation yield (WLXe = 15 eV, WLAr = 24 eV)
- Position reconstruction capability
 - cm in single phase
 - mm in TPC mode, better in z
- Good particle identification
 - PSD & Ionisation/Scintillation ratio

MiniCLEAN Detector

- Single phase LAr/LNe (solar neutrino capability)
- 180kg fiducial volume; PSD discrimination for background rejection
- Wavelength shifter on acrylic plugs
- PMT Cassette into steel vessel

Depleted Argon

- Cosmic ray production of ^{39}Ar in the atmosphere
 - Beta decay (565 keV; $T_{1/2} = 269$ years)
 - Atmospheric argon has 8×10^{-16} $^{39}\text{Ar}/\text{Ar}$
 - Creates activity of 1 Bq/kg: limits size and sensitivity of detectors
- ^{39}Ar depleted Ar is available from deep reservoirs underground where cosmic ray production suppressed
 - Depletion of >100 observed
- 75 kg (of 110kg) collected
 - 0.5kg/day
 - Expansion to >10 kg/day underway

Cryogenic Extraction Column

PICASSO Technique

- 150 μm droplets of C_4F_{10} dispersed in polymerised gel *
- Droplets superheated at ambient T & P ($T_b = -1.7^\circ\text{C}$)
- Radiation triggers phase transition
- Events recorded by piezo-electric transducers
- Operating temperature determines energy threshold

Main attractive features:

- low threshold $45^\circ\text{C} \rightarrow E_{\text{th}} = 2 \text{ keV}$
- inexpensive! 0.19 k\$/kg (C_4F_{10})
- insensitive to γ - background

* Inspired by personal neutron dosimeters
@ Bubble Technology Industries, ON

Slide from V.Zacek

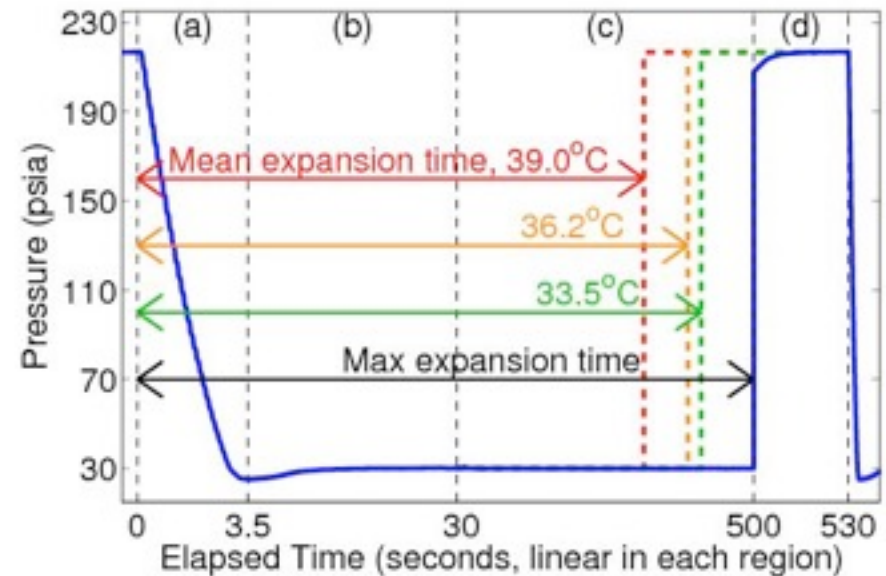

Detector response

- Threshold detectors, depend on temperature
- Calibrate detector response for various incident species
 - mono-energetic neutron beams
 - poly-energetic neutron sources
 - alpha/nuclear recoils

Principle of Operation: Bubble Chamber

1. Lower the pressure to a superheated state.

2. See the bubble:

- Cameras trigger. record position, multiplicity
- Microphones record acoustic trace
- Fast pressure transducer recording.

3. Raise pressure to stop bubble growth (100ms), reset chamber (30sec)

COUPP: bubble nucleation

- Target material CF_3I
 - provides spin dependent (F) and spin independent (I) sensitivity
- Energy threshold determined from Seitz 'hot-spike' model of bubble nucleation
 - benchmarked against calibration data
 - alphas used as a cross check

PICO-2L

First joint PICO detector: a 2-litre detector filled with C_3F_8

C_3F_8 has better fluorine sensitivity, lower threshold, more stable chemistry

Alpha Acoustic Discrimination

- Discovery of acoustic discrimination between recoils and alphas in PICASSO (Aubin et al., New J. Phys.10:103017, 2008)
 - **Nuclear recoils** deposit their energy over tens of nanometers.
 - **Alphas** deposit their energy over tens of microns.
- In bubble chambers alphas are several times louder due to the expansion rate difference.

The CDMS-II Detectors

CDMS Collaboration

- Discrimination through
 - recoil E (Heat), ionisation, timing
 - TE tungsten athermal phonon sensors
- Guard ring, x-y sensitive, close packing
- ~ton.d exp. @ Soudan (4.8kg Ge 1.1kg of Si)

SuperCDMS iZIPs

- ▶ Ultrapure Ge and Si crystals operated at ~ 40 mK
- ▶ Read out athermal phonon and charge signals
- ▶ Phonons give total energy
- ▶ Ratio of charge/phonon discriminates bulk gamma and nuclear recoil events
- ▶ Outer charge and phonon rings remove outer surface events
- ▶ Interleaved 2-sided charge sensors remove face events

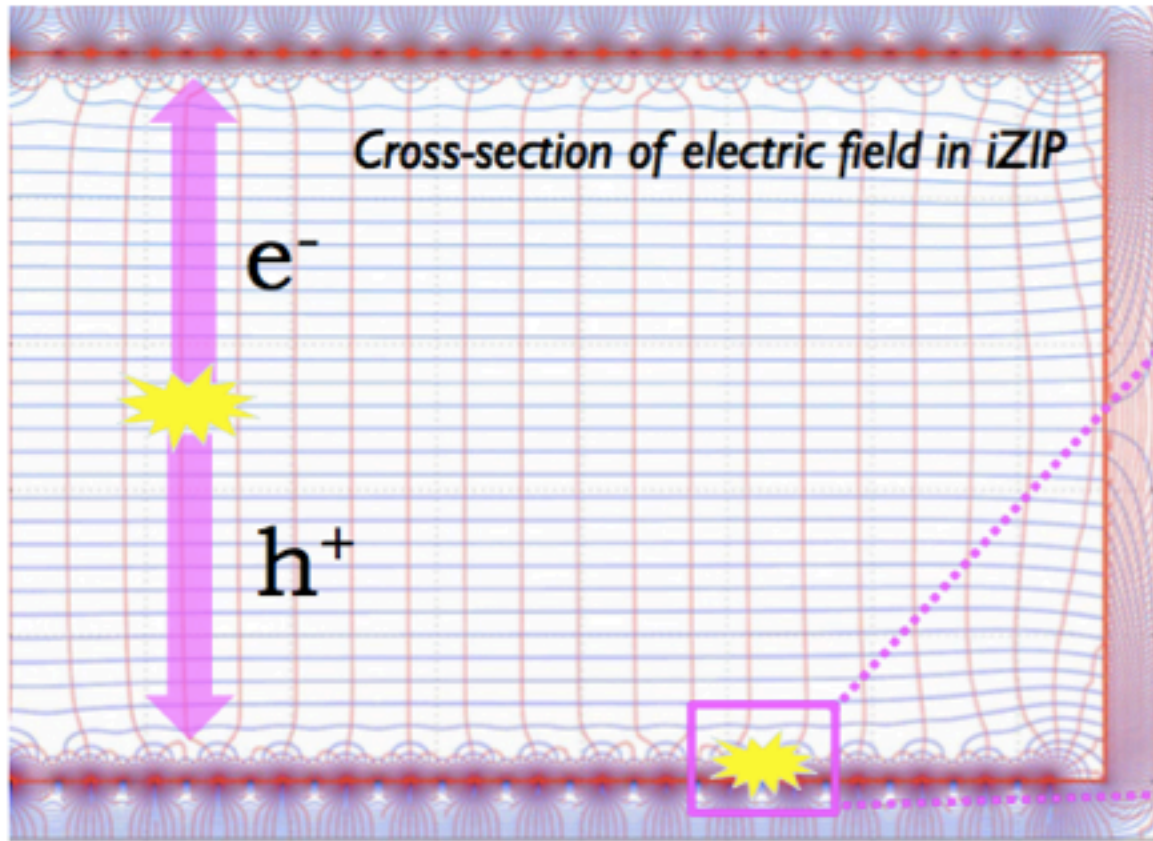

SuperCDMS Soudan: 8 phonon, 4 charge chans
 SuperCDMS SNOLAB: 12 phonon, 4 charge

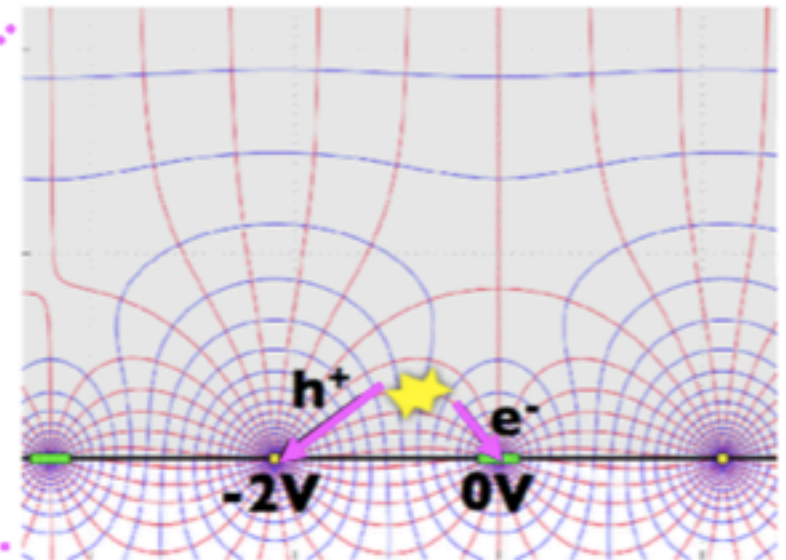

SuperCDMS iZIP surface rejection

iZIP: Interleaved phonon and charge sensors on both sides

Bulk events: charge collected on both iZIP faces

Surface events: only detect charge on one face

iZIPs have > 30X better surface event rejection w/ 50% better efficiency to WIMPs compared to CDMS-II ZIPs!

- The SNOLAB science programme requires advanced instrumentation to search for rare interactions and weak processes
- Challenges include
 - Minimal radiation backgrounds in detectors
 - High efficiency detection (single photon/phonon)
 - Particle discrimination (esp. neutrons and alphas)
- Techniques developed include
 - High light yield liquid noble gas
 - Low threshold solid state
 - Low threshold bubble chamber
- Common requirements for the programme include
 - Low radiological background assay capabilities (Ian Lawson)
 - Low radiological background environments (Chris Jillings)
