GridPPP UK Computing for Particle Physics

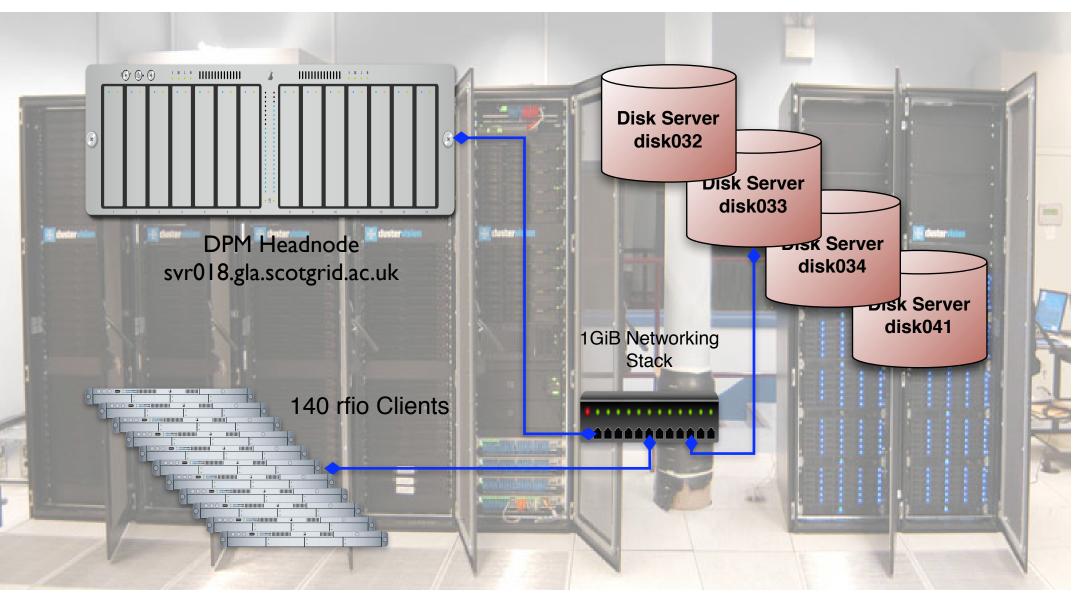

# **Optimising LAN access to grid** enabled storage elements

# Introduction

- Processing HEP data in a grid environment happens in two phases: • Gridftp transfer over the wide area network to a site's grid storage element
- Here we examine the performance of simulated physics analysis code on the LAN

## Test setup

- We utilised the ScotGrid Glasgow production WLCG site (UKI-SCOTGRID-GLASGOW) • This site uses the gLite Disk Pool Manager software for its
  - storage system
  - The site has a dedicated DPM headnode and 9 production disk servers with 90TB of storage • rfio client side software was run on up to 100 hosts,
  - substantially stressing the system

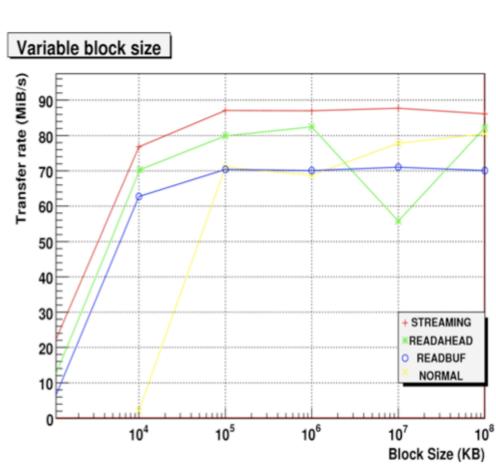

# **Client measurements**

### **RFIO modes tested**

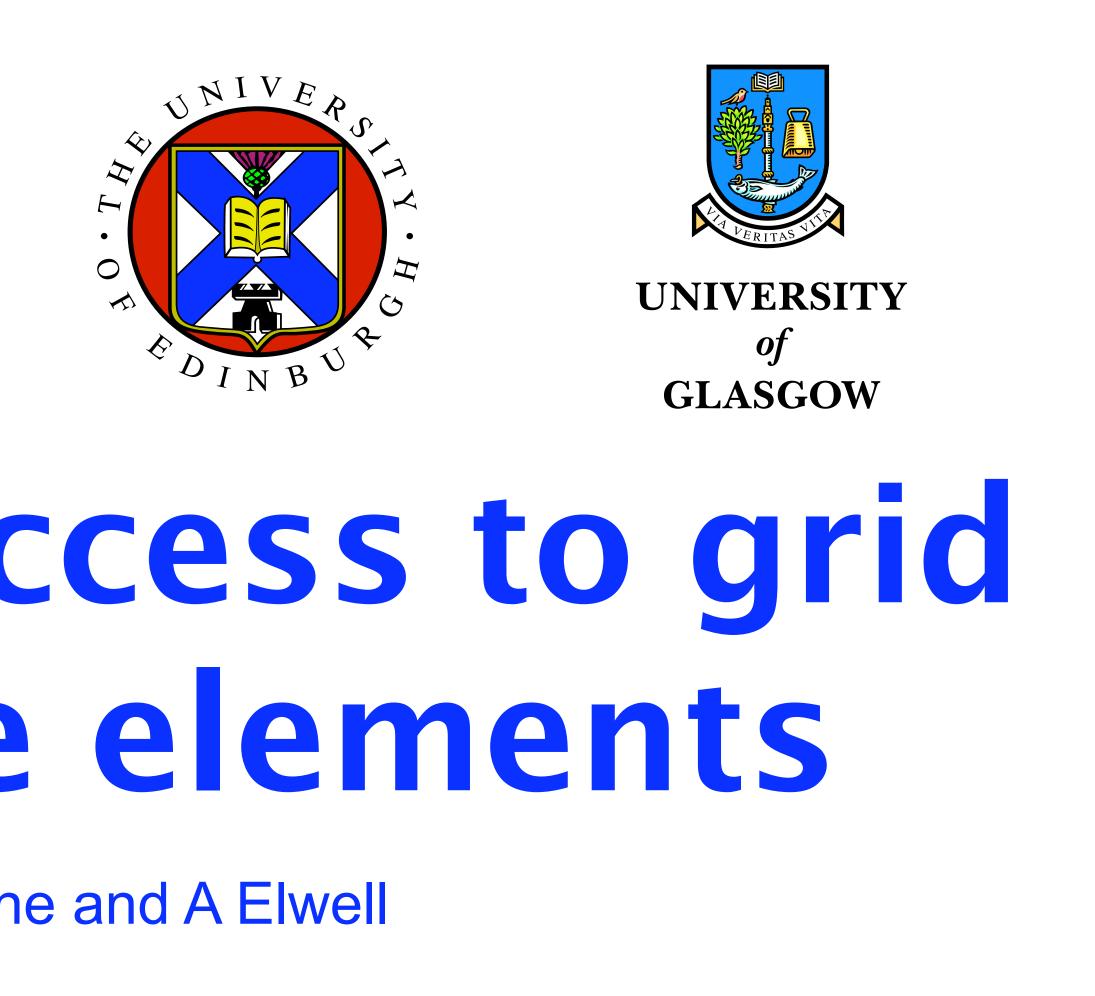

- NORMAL one call per read • READBUF – fills internal buffer to service requests
- READAHEAD user internal buffer and reads until EOF
- STREAM separate TCP streams for read/control

# **Transfer rate vs. RFIO block size**

# Conclusions

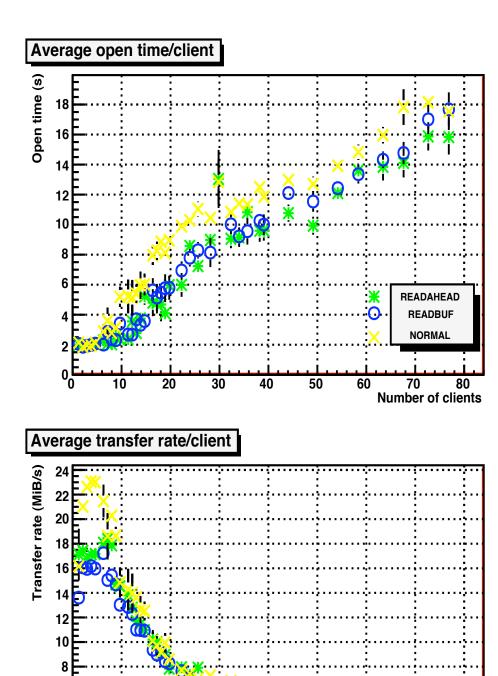

G A Cowan, G A Stewart, B Dunne and A Elwell

• POSIX-like random access to perform physics analysis tasks.

- Sequential reading of data. **RFIO\_STREAM** mode is fastest, however all modes benefit greatly from reading with block sizes of greater than 10MB.

## **Complete File** Reads

**RFIO** performance for complete file reads. Here it can be seen that NORMAL mode is poorer than all others. (N.B. For this test data was spread over 4 servers.)

# **Server Measurements Open time**

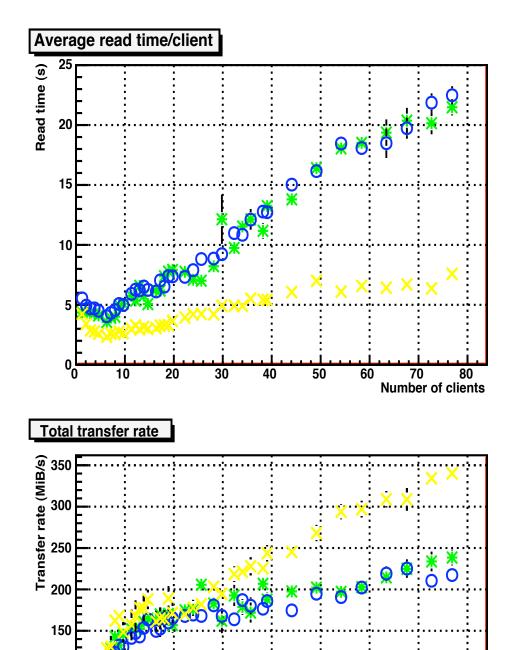

The red histogram shows the distribution of file open times for <23 simultaneous clients. The black histogram shows the case for >23 clients. This shows how the DPM response time changes under load. N.B. all clients start with a file open call within 1s in our tests.

- Utilising STREAM mode is beneficial for a single client when reading entire files, though READBUF anf READAHEAD also perform well.
- However, when many clients are expected to make partial reads from a site, NORMAL mode gives a better rate. • A data read block size of at least 10MB helps all reading modes.
- The authors would like to thank all those who helped in the preparation of this work. Funding for this work was provided by STFC/PPARC via the GridPP project. G Stewart is funded through the EU funded EGEE project.

STREAMING READAHEAD

> READBUF NORMAL

> > Number of clients

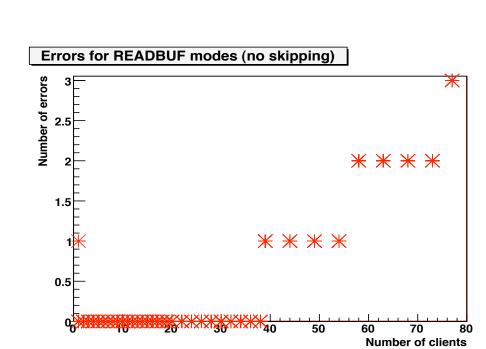

### **Partial File Reads RFIO** performance for simulated physics analysis (reading 10% of a file). Here it can be seen that NORMAL mode obtains the highest overall read rate, because with **READBUF** and **READAHEAD** data is read from the server which is not used by the client. (N.B. For this test data was spread

over 4 servers.)

# File access errors

10 20 30 40 50 60 70 80

In the case where the access to the file is sequential and with a buffer size of 1MB, a small number of errors were recorded for RFIO\_READBUF mode. This is a significant improvement compared to versions of DPM before 1.6.5 where the error count grew rapidly after ~20 clients

**Server load** 

Percent	disk036.gla.scotgrid.ac.uk CPU last hour 100↑	RRDTOO
		OL / TOBI
	the second s	
	13:40 14:00 14:20	21
	User CPU 🔲 Nice CPU 📕 System CPU 🔲 WAIT CPU Idle CPU	

On disk servers network capacity limits the overall transfer rate when complete files are being streamed; however, when partial reads are made i/o wait quickly dominates the load, and the network limit is not reached.

# **Further Work**

• Server i/o and network optimisations.

- Testing evil client scenarios for DPM robustness.
- Running experiment analysis code.
