

# *SHiP: a new facility for searching for long-lived neutral particles and studying the tau neutrino properties*

## *Search for **H**idden **P**articles*

Géraldine Conti (CERN)  
on behalf of the SHiP collaboration

27<sup>th</sup> Rencontres de Blois, June 3<sup>rd</sup> 2015

# Energy versus Intensity Frontiers

- **Experimental facts** of *Beyond Standard Model (BSM)* physics (neutrino masses, excess of matter over antimatter in the universe,...)
- **Theory motivations** for BSM physics (hierarchy problem, mass pattern,...)

*Long-lived neutral (hidden) particles*  
are predicted in many BSM models.

We can look for them at:

**Energy frontier :**

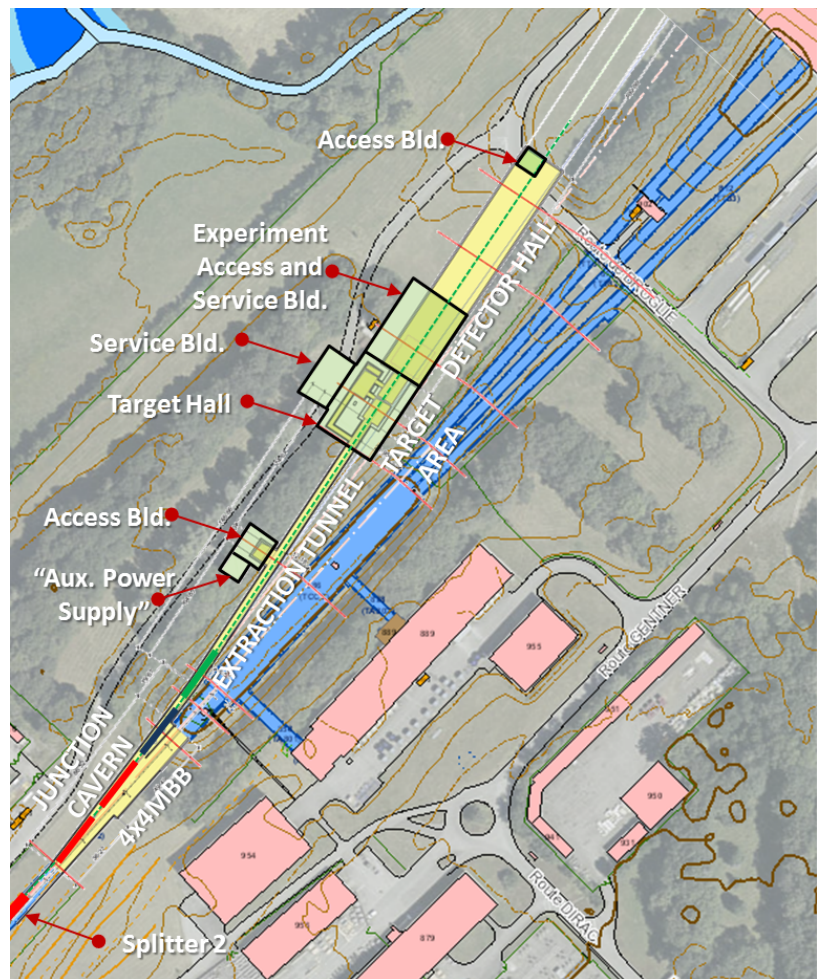

**Heavy** particles  
→ look into **higher energy** events

**Intensity frontier :**

**Light** particles  
→ search for **rare** events  
associated with them

**SHiP : masses below  $O(10)$  GeV**

# Proposal for a new facility at the SPS

- **400 GeV protons** from SPS,  $E_{CM}=27$  GeV

**Spill** =  $4 \times 10^{13}$  protons on target per **cycle** of 7.2s with **slow beam extraction** (1s)

reduces **detector occupancy**,  
hence combinatorial background

reduces **heat load of the target**

- **$4 \times 10^{19}$**  protons on target per year (~200 days of running)

# The SHiP experiment

## Example: long-lived neutral particles ( $N_{2,3}$ )

# The Target

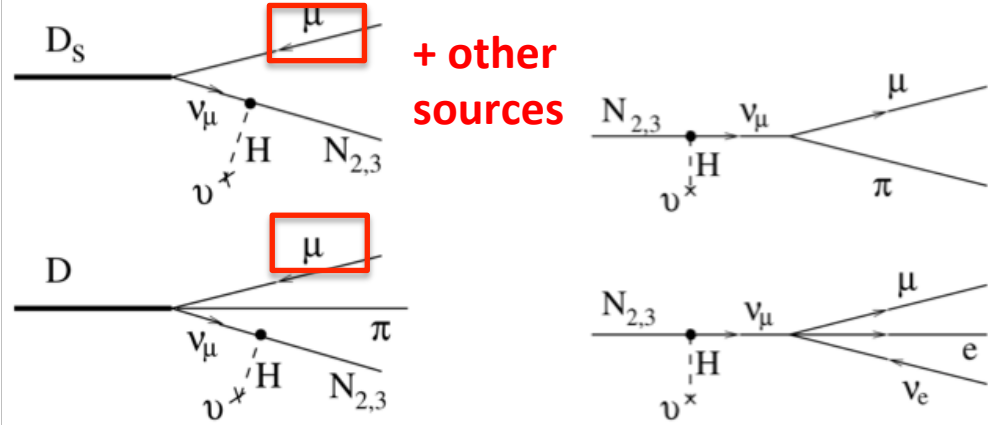

## Example: long-lived neutral particles ( $N_{2,3}$ )

- **heavy** material to stop  $\pi/K$  before they decay
- **Challenging** due to high average beam power deposited on target
  - 2.56 MW during spill of 1s (peak)

# The Muon filter

## Example: long-lived neutral particles ( $N_{2,3}$ )

- **Active  $\mu$  filter** (50m) made of 2 magnets ( $B_y = 40$  Tm to bend out 350 GeV m beyond the 5m vacuum vessel aperture)

- **Reduce the  $\mu$  flux** to  $<100k \mu/\text{spill}$

# The $\nu_\tau$ detector

- **OPERA-type**  $\nu$  target in B-field
  - $\mu$  flux :  $10^3 \mu/\text{mm}^2$  in 6 months
- RPC and drift tubes for  $\mu$  measurements

# The vacuum vessel

## Example: long-lived neutral particles ( $N_{2,3}$ )

- $10^{-6}$  mbar **vacuum** to suppress the  **$\nu$  interactions**
- **Elliptical** (5m x 10m) to avoid the large horizontal  **$\mu$  flux**
- Double-wall structure, space filled with **liquid scintillator** to tag background entering **from the sides**

# The spectrometer

## Example: long-lived neutral particles ( $N_{2,3}$ )

- Uses **existing technologies**
- **Usual layers:**
  - tracking system with B-field to reconstruct signal
  - ECAL and  $\mu$ -chambers for  $e/\gamma$  identification,  $\pi^0$  and  $\eta$  reconstruction
  - HCAL for  $\pi/\mu$  separation

# Physics cases

- Before LHC Run1, the idea of **naturalness** was very popular: the *new physics scale must be close to the Higgs scale* → *possible scenarios*

**LHC Run2** is sensitive to it

**OR Intensity frontier facilities (SHiP)** are sensitive to it (scale of NP not always  $\approx$  mass of new particles!)

**OR No new physics scale**

*Portals = possible interactions between new physics (hidden sector) and the SM particles*

**Vector portal    Scalar portal    Neutrino portal    Axion portal**

↓  
*SHiP can test this (example given later)*

*Beyond portals :*  
**SUSY**

Models tested	Final states
Neutrino portal, SUSY neutralino	$l\pi, lK, l\rho$ ( $l=e,\mu,\nu$ ) ( $\rho^+ \rightarrow \pi^+\pi^0$ )
Vector, scalar, axion portals, SUSY sgoldstino	$e^+e^-, \mu^+\mu^-$
Vector, scalar, axion portals, SUSY sgoldstino	$\pi^+\pi^-, K^+K^-$
Neutrino portal, SUSY neutralino, axino	$l^+ l^- \nu$
Axion portal, SUSY sgoldstino	$\gamma\gamma$
SUSY sgoldstino	$\pi^0 \pi^0$

# The Neutrino portal

- Example of one BSM theory with no new physics between Fermi and Planck scales: the  **$\nu$ MSM** [T. Asaka, M. Shaposhnikov, PL B620 \(2005\) 17](#)

	2.4 MeV $\frac{2}{3}$ Left <b>u</b> Right up	1.27 GeV $\frac{2}{3}$ Left <b>c</b> Right charm	171.2 GeV $\frac{2}{3}$ Left <b>t</b> Right top
Quarks	4.8 MeV $-\frac{1}{3}$ Left <b>d</b> Right down	104 MeV $-\frac{1}{3}$ Left <b>s</b> Right strange	4.2 GeV $-\frac{1}{3}$ Left <b>b</b> Right bottom
	$<0.0001$ eV 0 Left <b><math>\nu_e</math></b> Right electron neutrino	$\sim 0.01$ eV 0 Left <b><math>\nu_\mu</math></b> Right muon neutrino	$\sim 0.04$ eV 0 Left <b><math>\nu_\tau</math></b> Right tau neutrino
	<b><math>N_1</math></b> sterile neutrino	<b><math>N_2</math></b> sterile neutrino	<b><math>N_3</math></b> sterile neutrino
Leptons	0.511 MeV -1 Left <b>e</b> Right electron	105.7 MeV -1 Left <b><math>\mu</math></b> Right muon	1.777 GeV -1 Left <b><math>\tau</math></b> Right tau

$N_{1,2,3}$  = heavy neutral lepton (HNL), heavy (RH) neutrinos, sterile neutrinos,...

**$N_1$**  is a dark matter candidate ( $m \approx O(1)$  keV)

- Compatible with XMM-Newton emission line at  $E \approx 3.6$  keV

[Astrophys.J.789, 13\(2014\),](#)  
[Phys.Rev.Lett. 113,25301](#)

**$N_2, N_3$**  give masses to neutrinos and produce baryon asymmetry of the Universe ( $m \approx O(100)$  MeV – GeV )

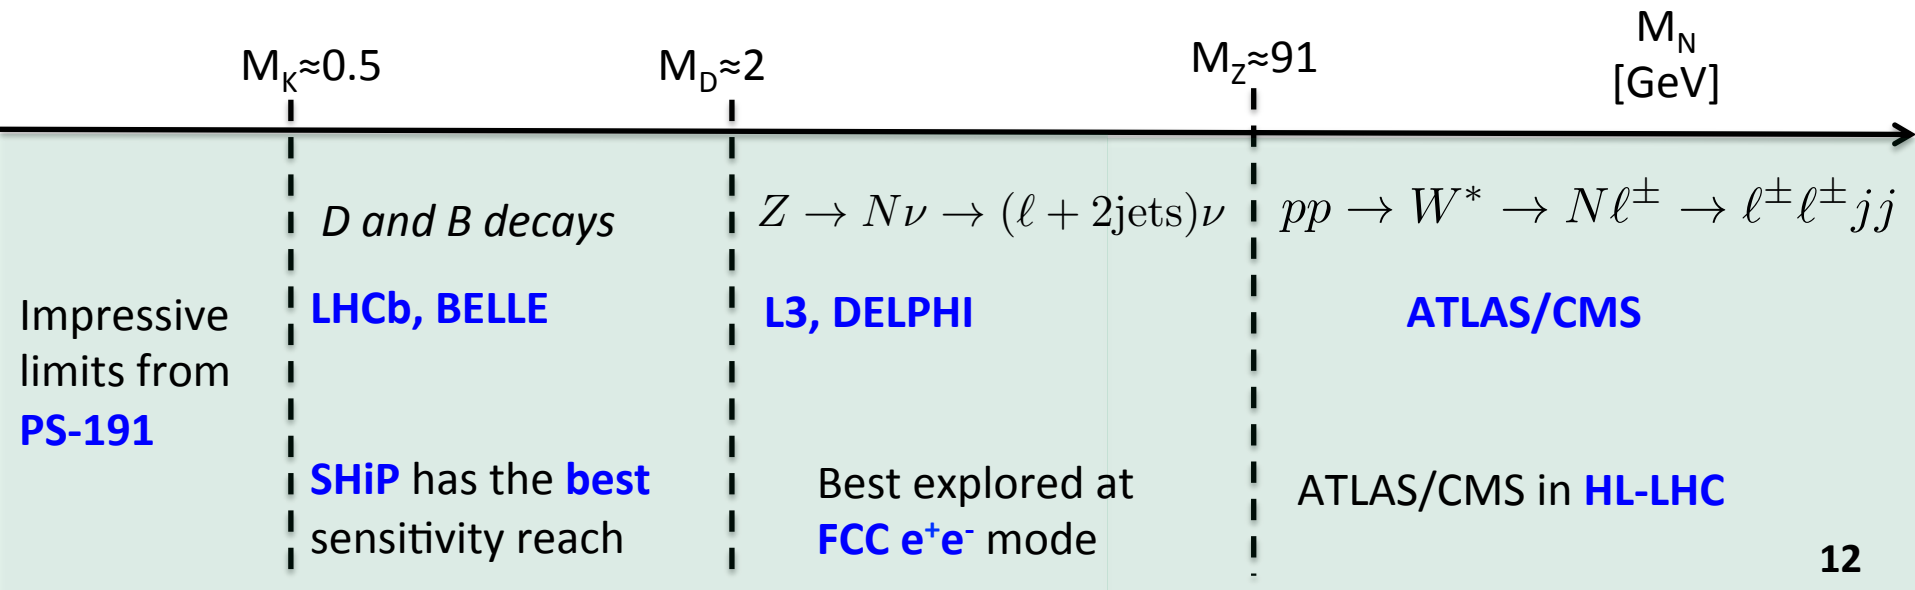

The Higgs gives masses to quarks, leptons, Z and W, and it inflates the Universe

# The Neutrino portal

- The SHiP limit are set **on  $N_{2,3}$**  ( $N_1$  is the dark matter candidate)

Coupling of the HNL to the SM particles  $\rightarrow |U_{ei}|^2$

- The region **above the kaon mass** is not yet well covered and **SHiP has the best sensitivity reach**

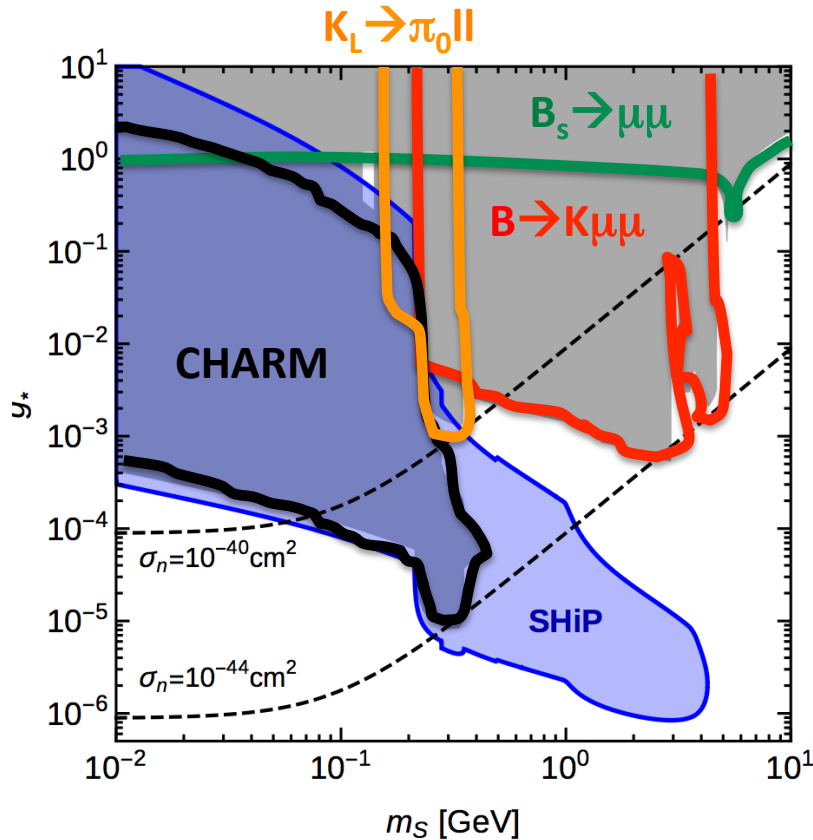

# The Scalar and Vector portals

Scalar portal :

S production : from B, D and K decays

S decays :  $S \rightarrow ee, \mu\mu, \pi\pi, KK$

SHiP will give insights for **masses < 10 GeV** and small couplings

Vector portal : dark photon ( $A'$ ) model

Production :

- 1) Meson decays
- 2) Bremsstrahlung ( $pp \rightarrow ppV$ )
- 3) QCD ( $q+q \rightarrow V$ ;  $q+g \rightarrow q+V$ )

Visibly Decaying  $A'$

SHiP will give insights for **masses > 200 MeV**, up to **3 GeV**.

# $\nu_\tau$ physics at SHiP

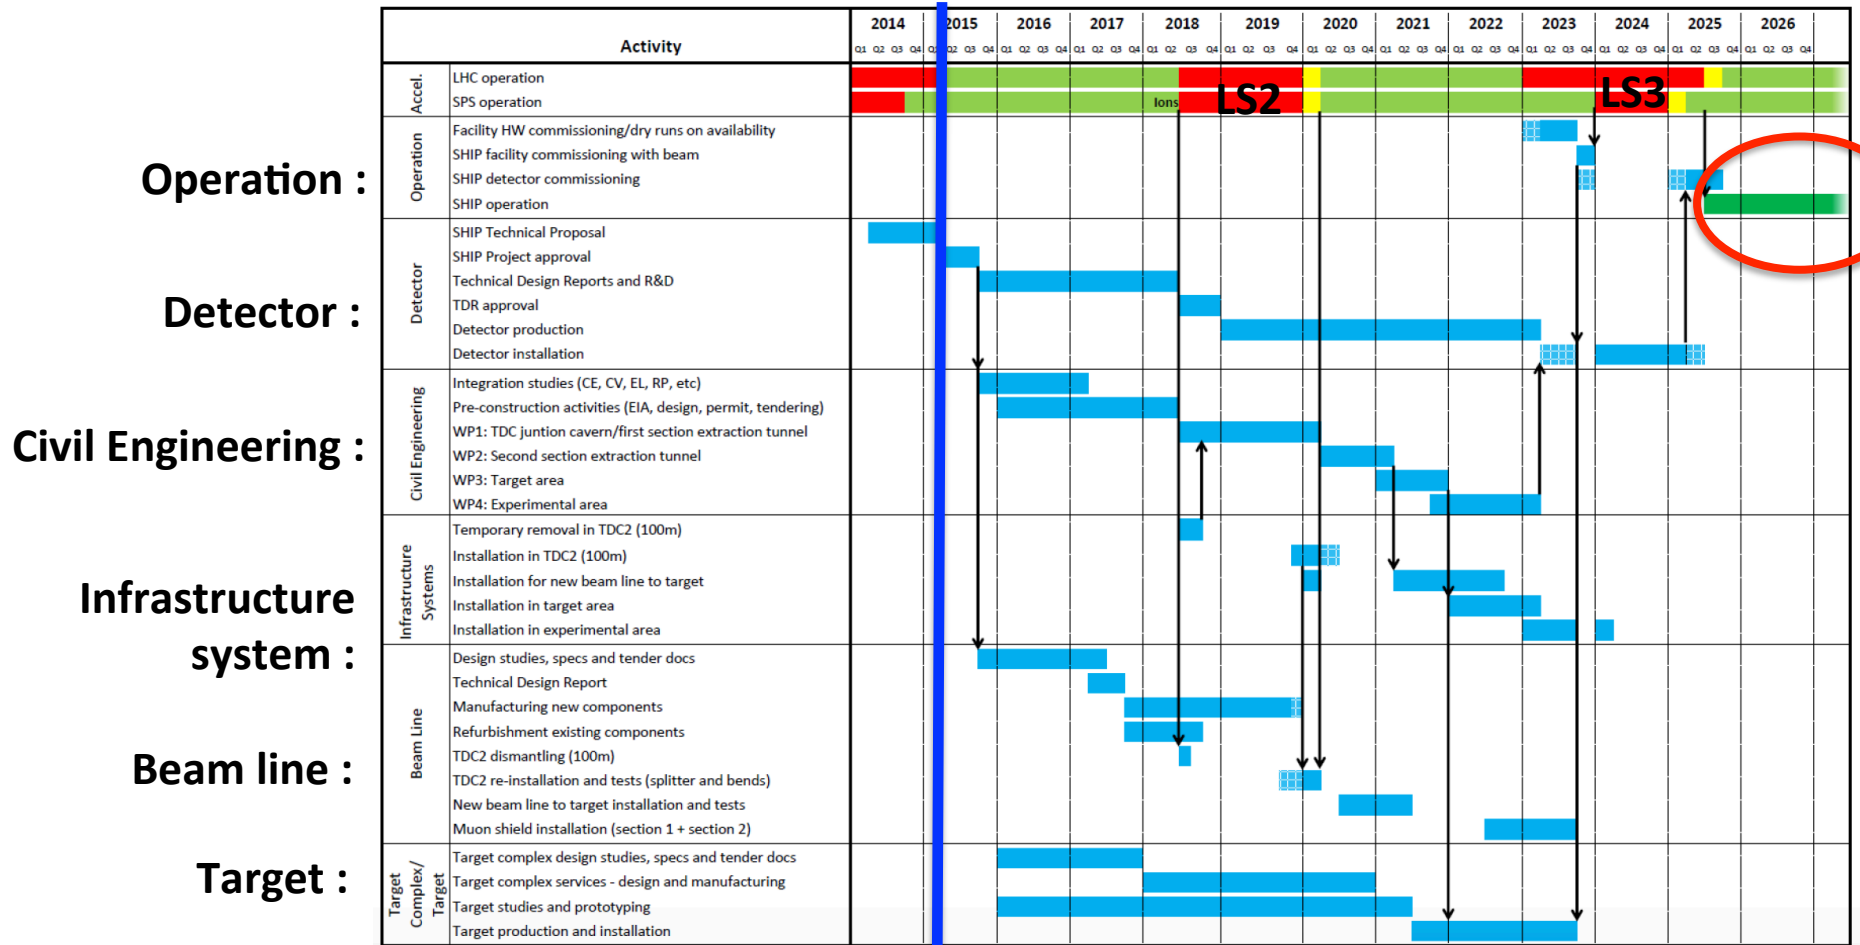

- $\nu_\tau$  observations

- DONUT (Tevatron) : 9 events (from charm) with 1.5 backgrounds
  - Not possible to distinguish the charge of the  $\tau$
- OPERA (Gran Sasso) : 4 events with 0 background
  - from  $\nu_\mu \rightarrow \nu_\tau$  oscillations, only  $\tau^-$  leptons

→ SHiP would increase **by three orders of magnitude** the current  $\nu_\tau$  sample, allowing for cross section measurements at **inclusive** and **differential** levels

- The anti- $\nu_\tau$  has never been observed
  - SHiP could **observe the anti- $\nu_\tau$**  by detecting the  $\tau^+$  lepton produced
- Structure functions **F4 and F5** in  $\nu_\tau$  and anti- $\nu_\tau$  charged current cross sections can be measured (deep inelastic scattering)
  - At incident energy  $E=20$  GeV, these terms account for 30% of the cross section

# Timescale

- CERN decision on the strategy with SHiP **within a year**
  - Weeks of **test beam** planned on SPS and PS this year to test detector technologies
- **10 years** from submission of Technical Proposal to data taking
- 5 years of data taking (**from 2025**) of **2x10<sup>20</sup> protons on target**

# Why signing up for SHiP ?

- could explore **with unprecedented sensitivity** phase spaces of “Beyond the Standard Model” physics that are of greatest interest in light of the LHC and astrophysical results, for example **heavy neutral leptons with masses below  $O(10)$  GeV**
- could provide important results **in the  $\nu_\tau$  sector**

- is rather **low-cost**

uses **existing** detector technologies

**recycles** material (Goliath magnet)

- takes the **lifetime** of a Swiss passport to become real !

***45 institutes in SHiP***  
***> 80 theorists***

# The crew members

# The target

- **Challenging** due to high average beam power deposited on the target
  - 2.56 MW during spill of 1s (peak)
  - ~350 kW averaged over 7s cycle
- **Hybrid** target, water cooled
  - 58cm of titanium-zirconium doped molybdenum
  - 58cm of pure tungsten, water cooled
  - **heavy** to **stop  $\pi/K$  before they decay**
- ~1.2m-long, 30x30cm<sup>2</sup> to **maximize shower containment**
- Embedded in **cast iron bunker** (440m<sup>3</sup>)

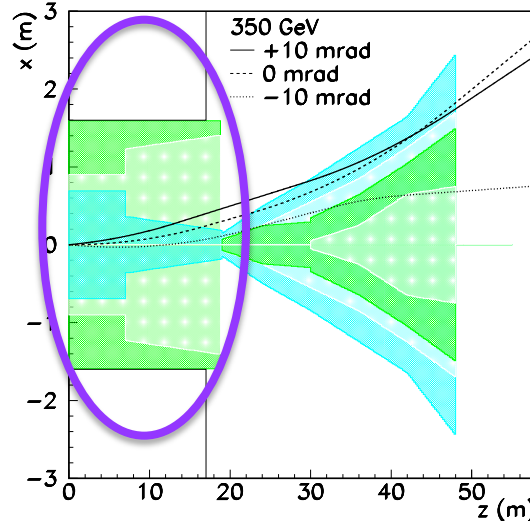

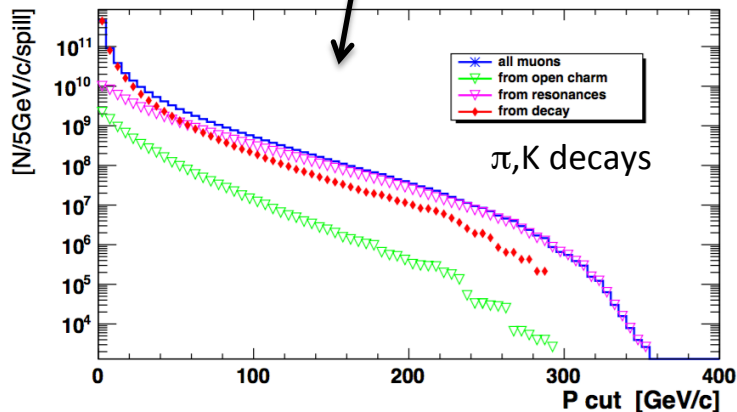

# The muon filter

- **Reduce the  $\mu$  flux** to  $<100k \mu/\text{spill}$  (also to reduce **occupancy** in the  $\nu_\tau$  detector)
- **Active  $\mu$  filter (50m)** made of **2 magnets** ( $B_y = 40 \text{ Tm}$  to bend out 350 GeV  $\mu$  beyond the 5 m vacuum vessel aperture)

**1<sup>st</sup> part** to separate  $\mu^+/\mu^-$ :

**2<sup>nd</sup> part** to remove the  $\mu$  bent back by the return field:

# The $\nu_\tau$ detector

from CERN  
H4 beam  
line

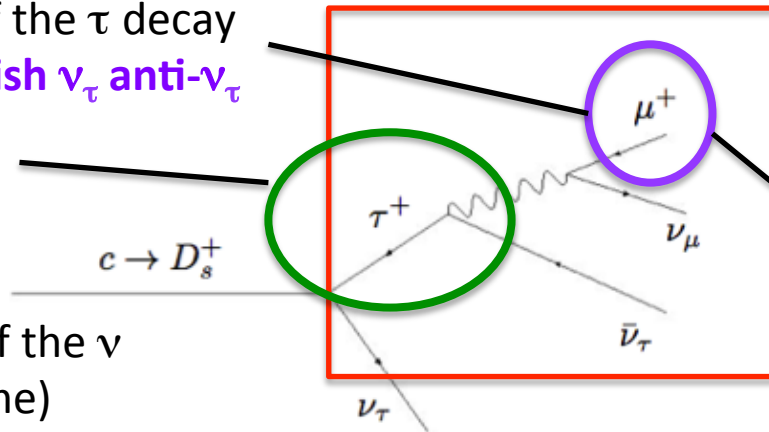

## OPERA-type modules in B-field

- lead and emulsion cloud chambers
- 1x1m, close to the beam line
- $\mu$  flux :  $10^3 \mu/\text{mm}^2$  in 6 months

look at the **charge** of the  $\tau$  decay products to **distinguish  $\nu_\tau$  anti- $\nu_\tau$**

**detection of  $\tau$  production and decay** to identify a  $\nu$  interaction:

(contained within a brick of the  $\nu$  target due to short  $\tau$  lifetime)

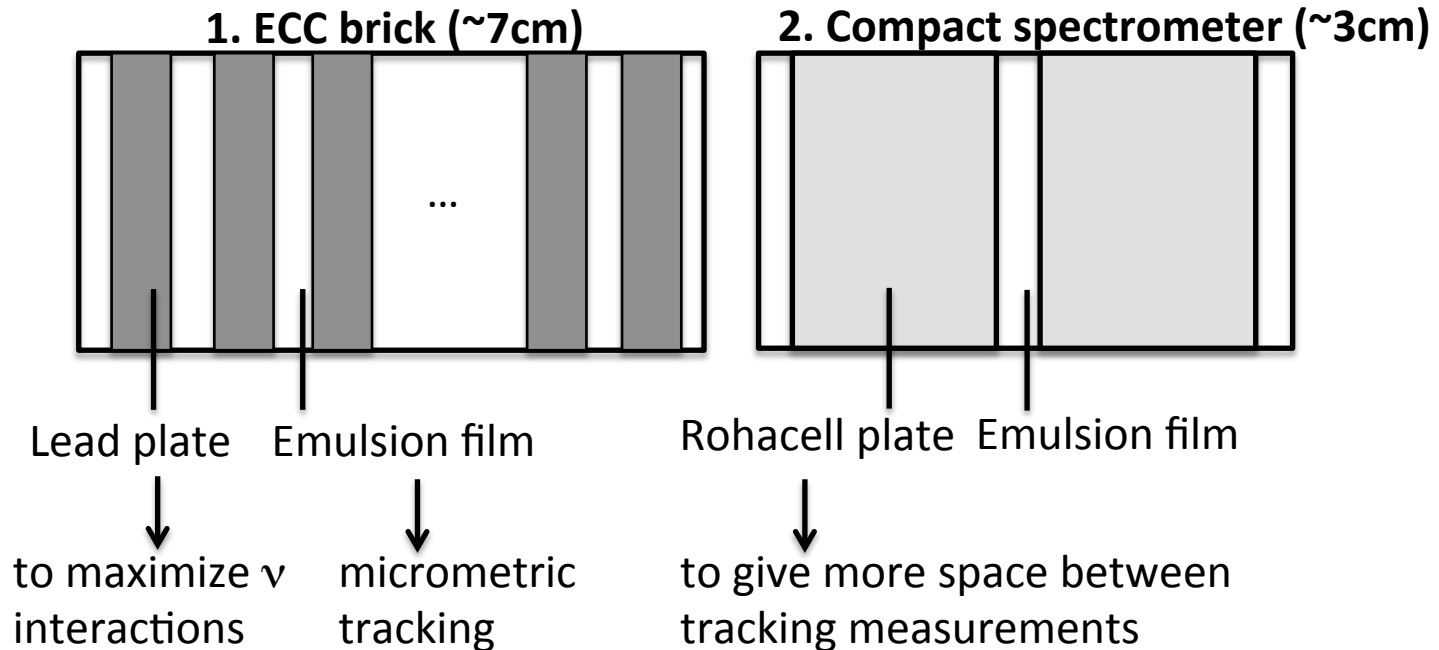

## RPC and drift tubes :

Identify  $\mu$  coming from  $\tau$  decays;  $\mu$  momentum measurement

# The $\nu_\tau$ detector : target

## OPERA-type modules (emulsion cloud chambers (ECC))

- A unitary cell of the neutrino detector has two parts :

**$\nu$  interaction** : identified through **detection of  $\tau$  production and decay** (contained within a brick due to short  $\tau$  lifetime)

**distinguish  $\nu_\tau$  anti- $\nu_\tau$**  : look at the **charge of the  $\tau$  decay** products

- hundreds of target units assembled together to achieve the ton scale for a very high resolution device

# The vacuum vessel

- **Veto tagger** just after  $\nu_\tau$  detector to tag indirectly **neutral K** produced by  $\nu$  and  $\mu$  interactions in the passive material and  **$\mu$  entering the vessel from the front**
- **Elliptical** structure to avoid the large  **$\mu$  flux deflected horizontally** by the  $\mu$  shield
- $10^{-6}$  mbar **vacuum** to suppress the  **$\nu$  interactions**

- Double-wall structure, space filled with **liquid scintillator** to tag background entering **from the sides**
- tracking detector to reject residual charged bkg **in the forward region ( $K_s^0, \dots$ )**

# The spectrometer

**Signal reconstruction and background rejection:** warm magnet (LHCb) with 0.65Tm bending power; tracker (NA62) with horizontal straws and stereo angle

**Veto anti-coincidence from combinatorial:** timing detector (50ps resolution)

**$e/\gamma$  identification,  $\pi^0$  and  $\eta$  reconstruction:** ECAL (Shashlik (sampling scintillator-lead structure read out by plastic WLS fibres), LHCb)

**$\pi/\mu$  separation:** hadronic calorimeter (similar technology as ECAL), muon detector (WLS fiber bars, MINOS)

# Vector Portal

- Existence of new vector states associated with new U(1) gauge groups :  $SU(3) \times SU(2) \times [U(1)]^n$
- LHC : strong limits provided that the coupling to the SM is large
- Light vector states (GeV) with small couplings to SM not well constrained
- Motivation: could provide solution to  $m_{g-2}$  discrepancy, explain the strong emission of 511 keV photons from the galactic bulge, also explain the observation of the rise in the positron flux as a function of energy.

# ALPS at SHiP

- Motivations for **axions** :
  - Particle that can solve the **strong CP problem of QCD**
- Large spontaneous symmetry breaking scale  $f_A$ 
  - small couplings
  - small mass  $m_A$  proportional to  $1/f_A$
- Wide range of (pseudo-)scalar particles with similar features to axions but different masses (called **axion-like particles** or **ALPS**)
  - needed in **string theory**
  - can **mediate to DM**

Particularly interesting decays :  $\gamma\gamma$ ,  $\mu\mu$

Coupling to fermions :

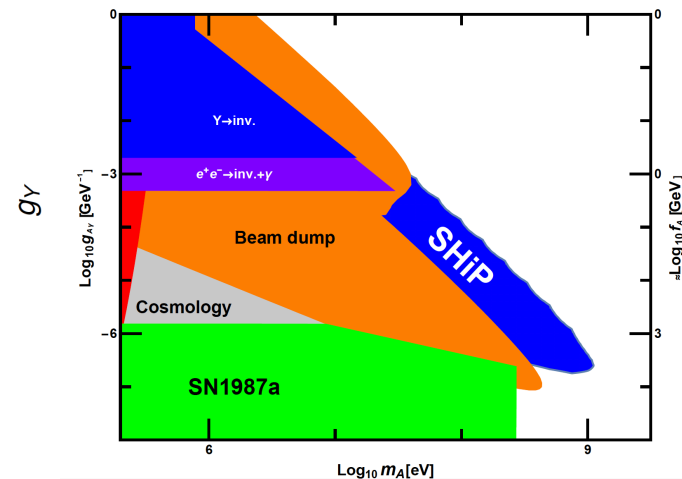

Direct ALP production from ALP-pion mixing

Indirect ALP production from B decays

combination

Coupling to photons/ gauge bosons :

# SUSY at SHiP : s-goldstinos (1)

- SUSY breaking may be accompanied **by s-goldstinos (pseudo-scalar P, scalar S)** with couplings  $\sim 1/(\text{SUSY breaking scale}) \rightarrow$  could have escaped detection !
- S-goldstinos are R-even, hence they may be **directly produced**. The production is dominated by gluon fusion.
- They can also be **indirectly produced** through meson decays

$$pp \rightarrow S(\text{gluon fusion}), S \xrightarrow{\text{long lived}} \ell^+ \ell^-, \pi^+ \pi^-, \pi^0 \pi^0$$

$$pp \rightarrow D + X \rightarrow S + X', S \xrightarrow{\text{long lived}} \ell^+ \ell^-, \pi^+ \pi^-, \pi^0 \pi^0$$

# SUSY at SHiP : neutralinos (2)

- R-parity violating light neutralinos**

- Stable neutralinos LSPs excluded in mass range [0.7eV,24GeV], as it would give too much dark matter  $\rightarrow$  mass range still allowed if neutralino decays (R-parity violation)

**Neutralino decays :**

- 1)  $K^+ l^+$
- 2)  $K_{S/L} \nu$

**Figure 6.1:** Relevant Feynman Diagrams for  $D^+ \rightarrow \tilde{N}_1^0 + l^+$ .

SHiP can probe sfermions in the region of **a few 10s of TeV**.

# SUSY at SHiP : axinos (3)

- In a supersymmetric version of axion models, the axion  $A$  has as fermionic partner the **axino**.
- The most direct constraints typically arise from the search for the axion itself. But if the axino is **light**, then it is interesting to **search for it directly**.
- If **R-parity is broken**, a **single axino** is produced together with a neutrino:

The axion LSP can decay to  $\gamma$  and  $\nu$  dominantly. In models with DSFZ-type interaction, they **can decay into  $l\bar{l}\nu$**  with a similar decay rate.

- If **R-parity is conserved**: pair production of SUSY particles

Mono- $\gamma$  or two-lepton **final state**

Figure 6.8: Neutralino to axino decay channels.

# F4, F5

charged current events. With the usual DIS variables:  $x \equiv Q^2/2p \cdot q$  and  $y \equiv p \cdot q/p \cdot k$ , where the momentum assignments are:

$$\nu_\tau/\bar{\nu}_\tau(k) + N \quad \rightarrow \quad \tau^-/\tau^+(k') + X \quad (7.1.2)$$

$$q^2 \equiv (k - k')^2 = -Q^2, \quad (7.1.3)$$

the tau neutrino and anti-neutrino charged current cross sections in terms of the structure functions  $F_1, \dots, F_5$  are [944]:

$$\begin{aligned} \frac{d^2\sigma^{\nu(\bar{\nu})}}{dx dy} = & \frac{G_F^2 M E_\nu}{\pi(1 + Q^2/M_W^2)^2} \left( (y^2 x + \frac{m_\tau^2 y}{2E_\nu M}) F_1 + \left[ (1 - \frac{m_\tau^2}{4E_\nu^2}) - (1 + \frac{Mx}{2E_\nu}) y \right] F_2 \right. \\ & \left. \pm \left[ xy(1 - \frac{y}{2}) - \frac{m_\tau^2 y}{4E_\nu M} \right] F_3 + \frac{m_\tau^2(m_\tau^2 + Q^2)}{4E_\nu^2 M^2 x} F_4 - \frac{m_\tau^2}{E_\nu M} F_5 \right), \end{aligned}$$

where  $+F_2$  applies to neutrino scattering and  $-F_2$  to antineutrinos.  $M$  and  $m_\tau$  are the nucleon and  $\tau$  lepton masses respectively,  $E_\nu$  is the initial neutrino energy and  $G_F$  is the Fermi constant. As we will see, at the lower  $\nu_\tau$  energies the SHiP experiment offers the first opportunity to measure the structure functions  $F_4$  and  $F_5$ . At the Born level, neglecting target mass corrections, the Albright-Jarlskog relations apply [944]

$$F_4 = 0, \quad (7.1.4)$$

$$F_5 = \frac{F_2}{2x}. \quad (7.1.5)$$

The QCD predictions for the DIS structure functions  $F_4$  and  $F_5$  are known up to NLO accuracy [945], including full dependence on heavy-quark masses, though. The detailed relationships between the five structure functions, including NLO QCD together with target mass and charm quark mass corrections, are discussed, for example, in Refs. [945–948].

# Backgrounds

- ◉ Discriminate residual background: with/out misidentification,  $X = X^\pm, X^0, X$ 
    - Inelastic scattering:  $\nu$  or  $\mu + N \rightarrow X + K_L \rightarrow \pi\mu\nu, \pi e\nu, \pi^+\pi^-, \pi^+\pi^-\pi^0$   
 $\rightarrow X + K_S \rightarrow \pi^0\pi^0, \pi^+\pi^-$   
 $\rightarrow X + n \rightarrow p e^- \bar{\nu}_e \quad \rightarrow X + \Lambda \rightarrow p\pi^-$   
 $n + N \rightarrow X + K_L \dots\dots$
    - Muon combinatorial
- Tracking + particle identification !
