

Cryogenic Detectors for HEP in Space and Related Requirements

Jan van der Kooij

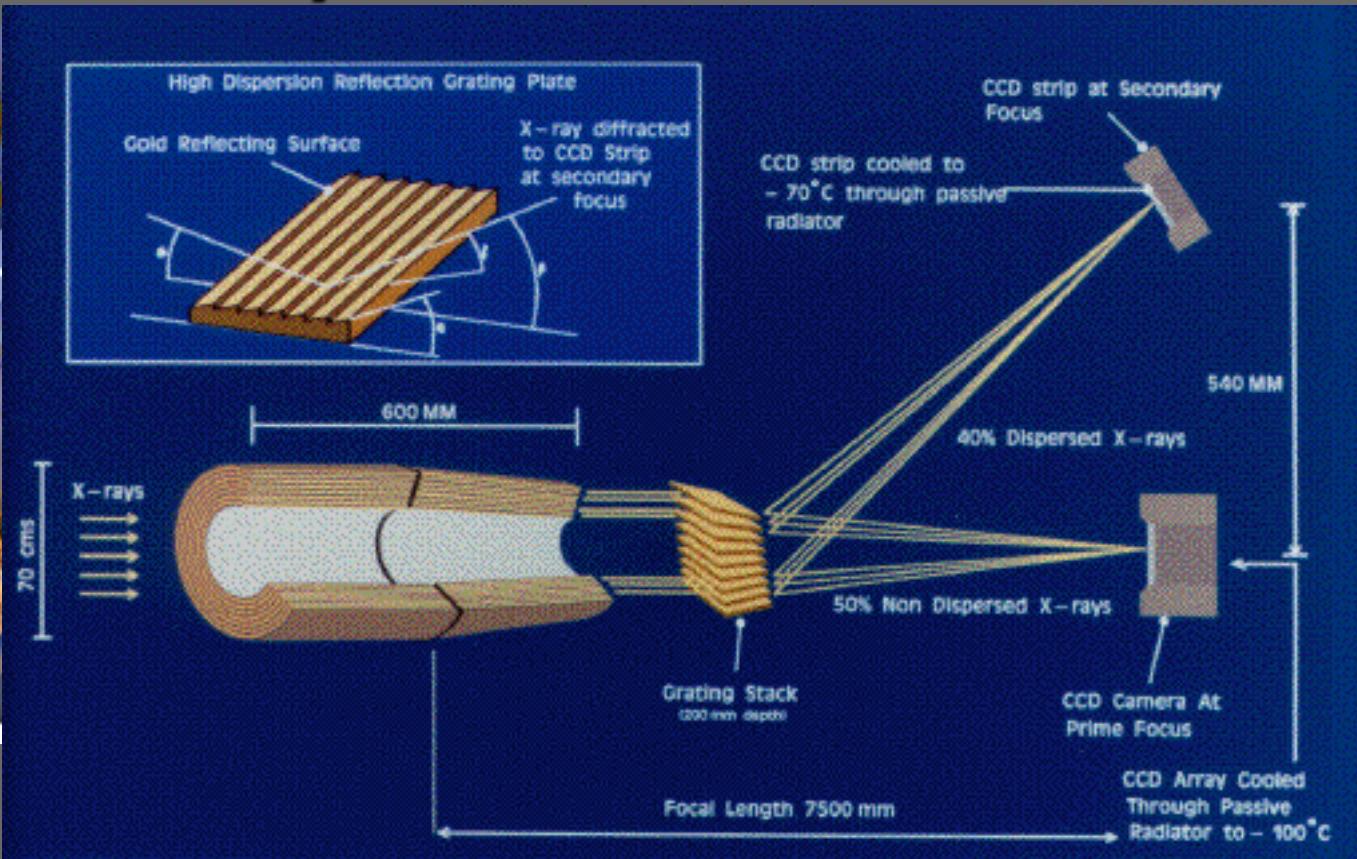

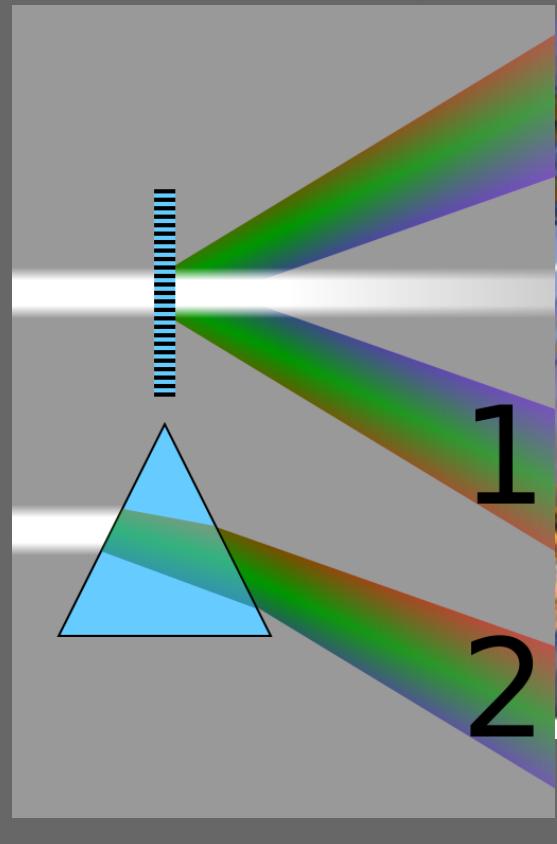

SRON

Netherlands Institute for Space Research

Netherlands Organisation for Scientific Research (NWO)

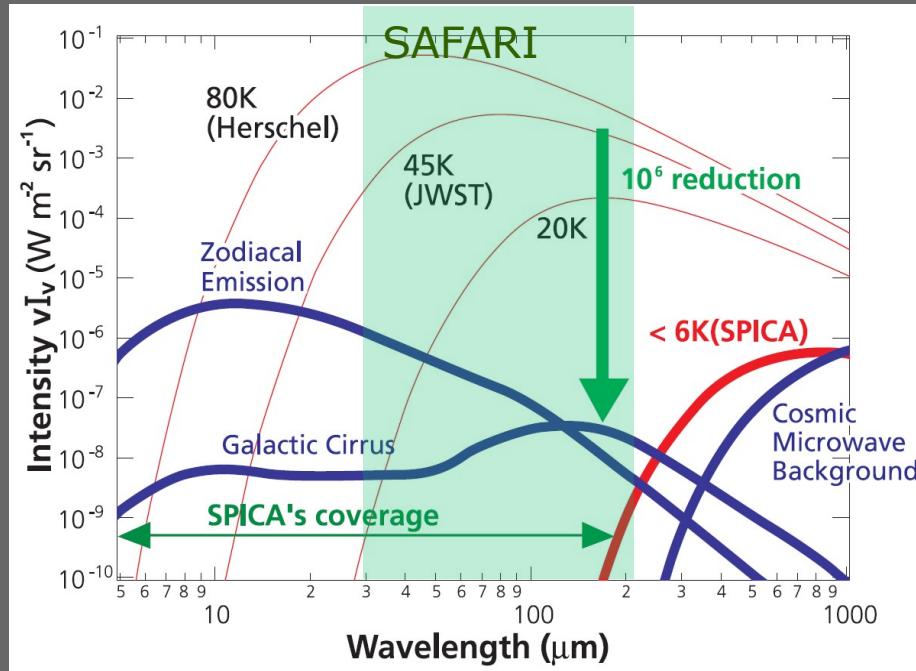

Why do we need cryogenic detectors at mK temperatures for space applications?

XMM X-ray observatory

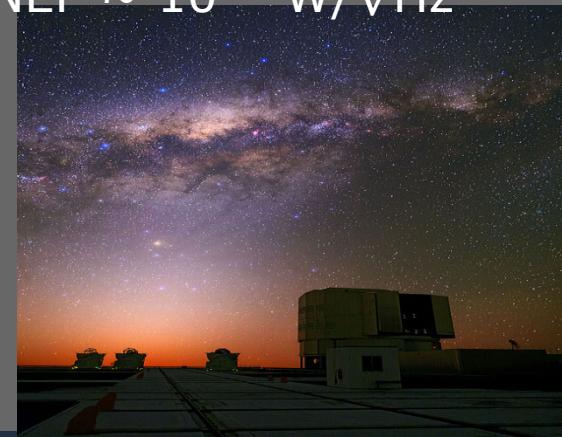

- In orbit since december 1999
- CCD detectors
- Grating spectrometers
- Energy resolution limited at high energies (20eV @ 2.1keV)
- Astronomy requires $\Delta E < 3\text{eV}$ @ 6keV

Far Infrared astronomy

- Far Infrared sensitivity limited by telescope emission
- Cold mirrors will reduce this telescope background
- Need for imaging sensors with high sensitivity
- SPICA:
 $\text{NEP} \sim 2*10^{-19} \text{ W}/\sqrt{\text{Hz}}$
- Ground based, warm optics:
 $\text{NEP} \sim 10^{-15} \text{ W}/\sqrt{\text{Hz}}$

How much is 10^{-19} W?

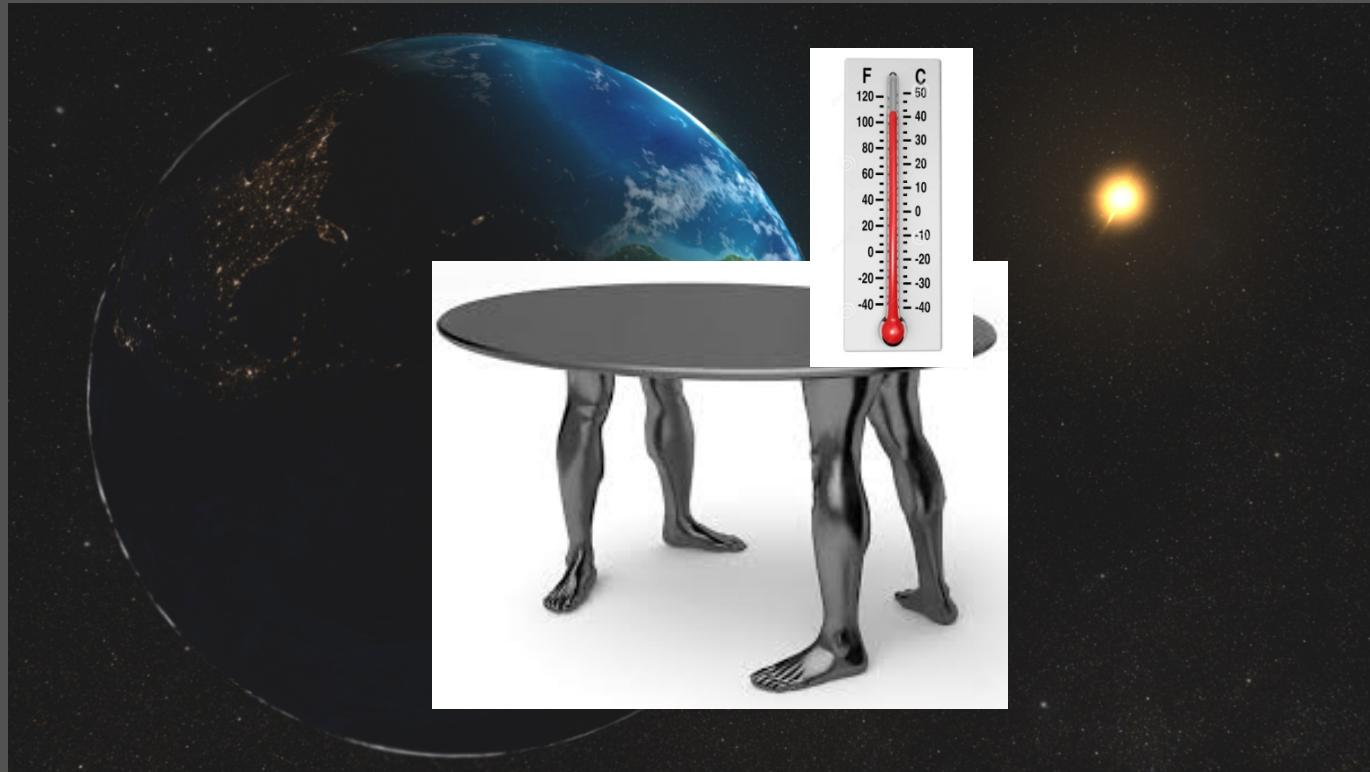

1m^2 telescope @ earth...

...observing a biking light @
the moon...

... provides $\sim 10^{-19}$ W in its focus

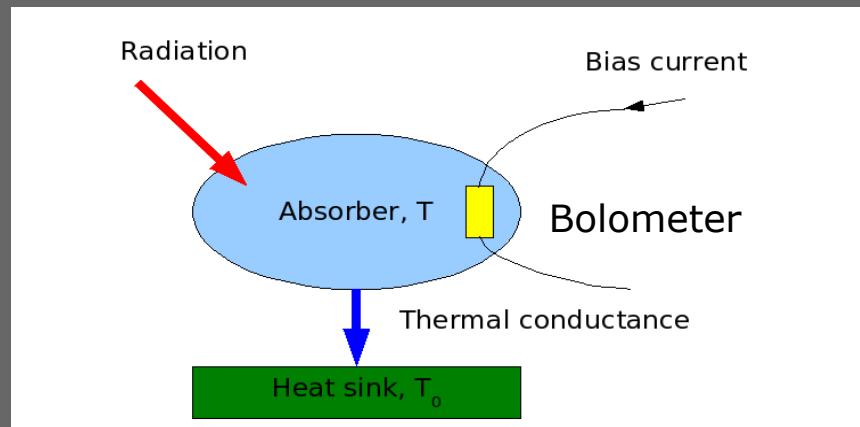

How can 10^{-19} W be detected?

- Cryogenic bolometers can do the job
- 10^{-19} W $\Leftrightarrow 2\mu\text{K}$ -> measurable
- Thermal isolation ~ 50 fW/K needed
- X-ray: $3\text{eV} = 5*10^{-19}$ J -> similar values
- Note: Sun provides $\sim 10^{15}$ K

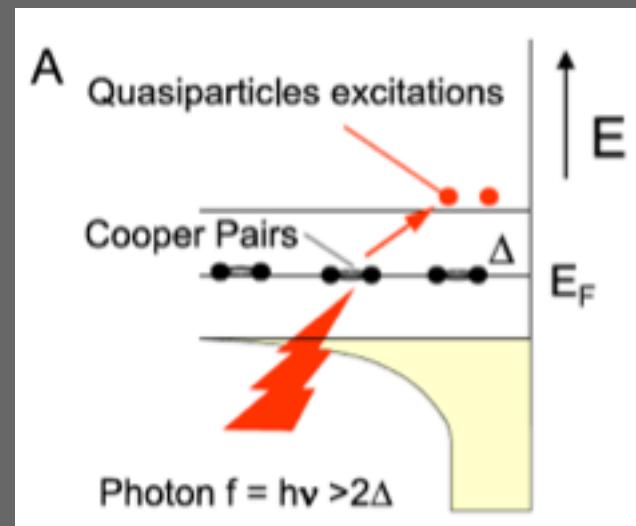

Equilibrium vs non-equilibrium detectors

Equilibrium (thermal) detectors

- Radiation heats isolated island
- Temperature change = signal
- ΔR : - semiconductor
- superconductor (TES)
- ΔH : - SQUID magnetometer
- Noise limit: statistics on number of phonons (shot noise)
- Operates @ $\sim 100\text{mK}$

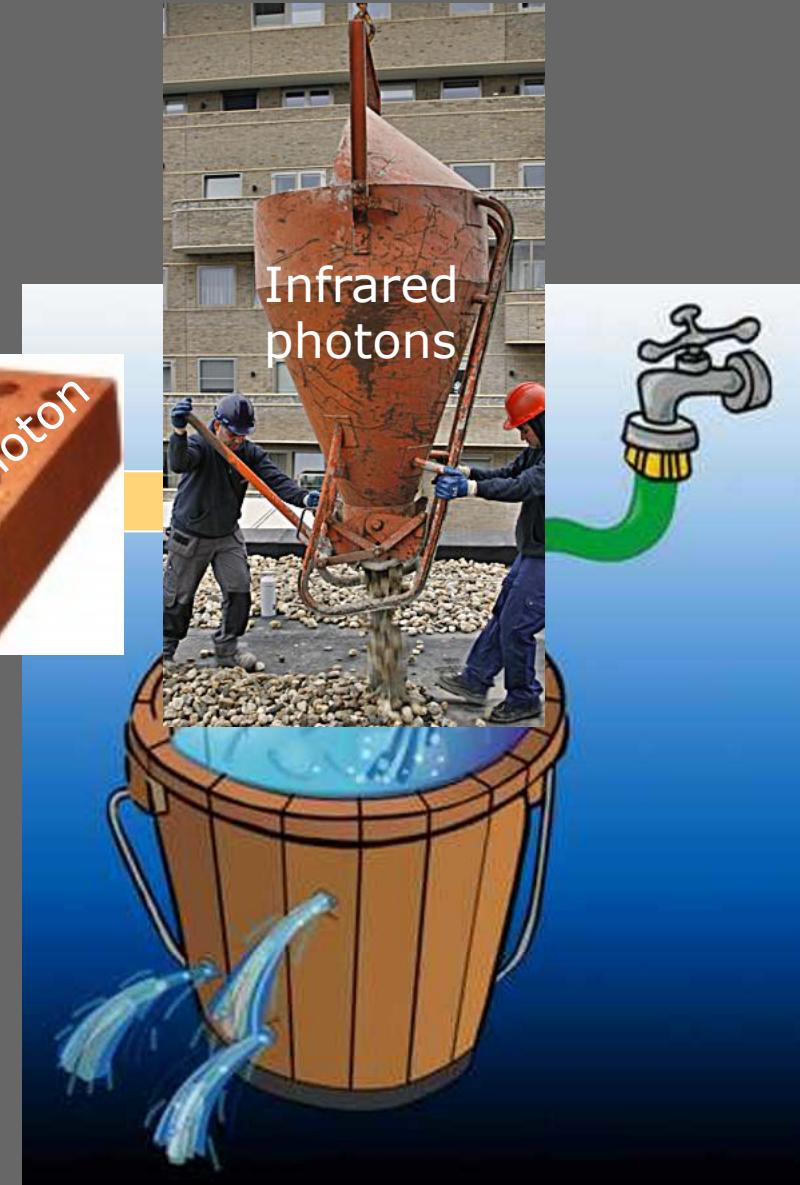

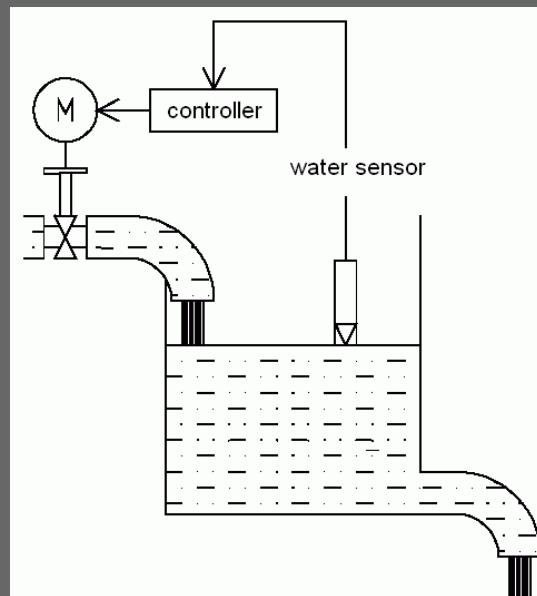

Non-equilibrium detectors

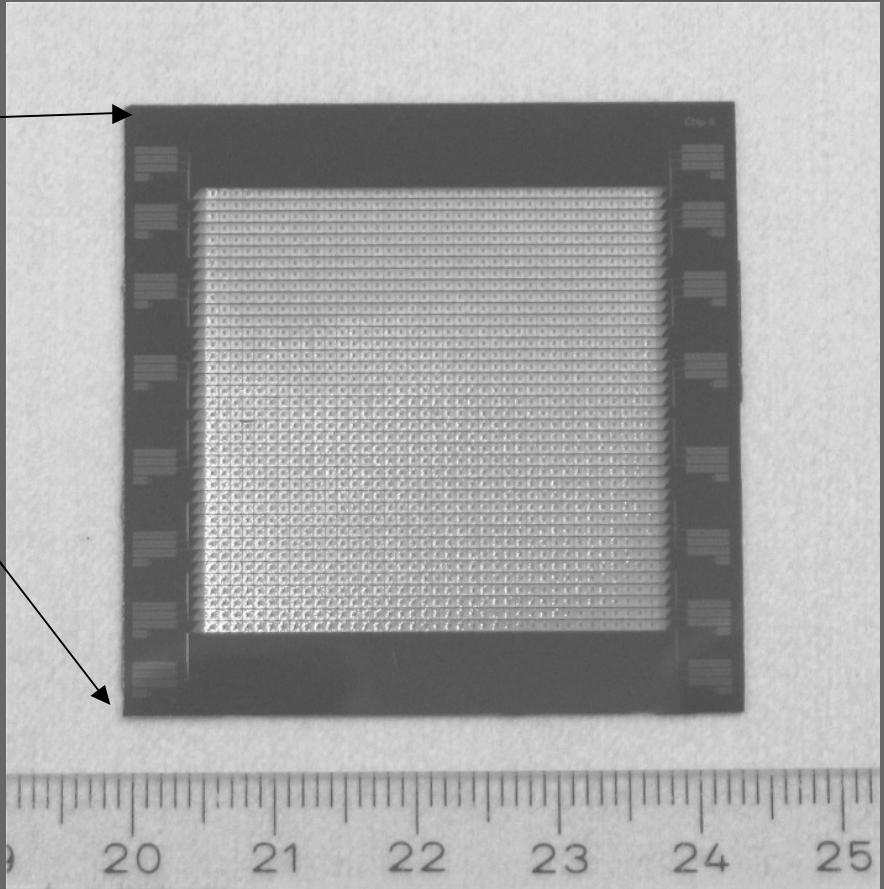

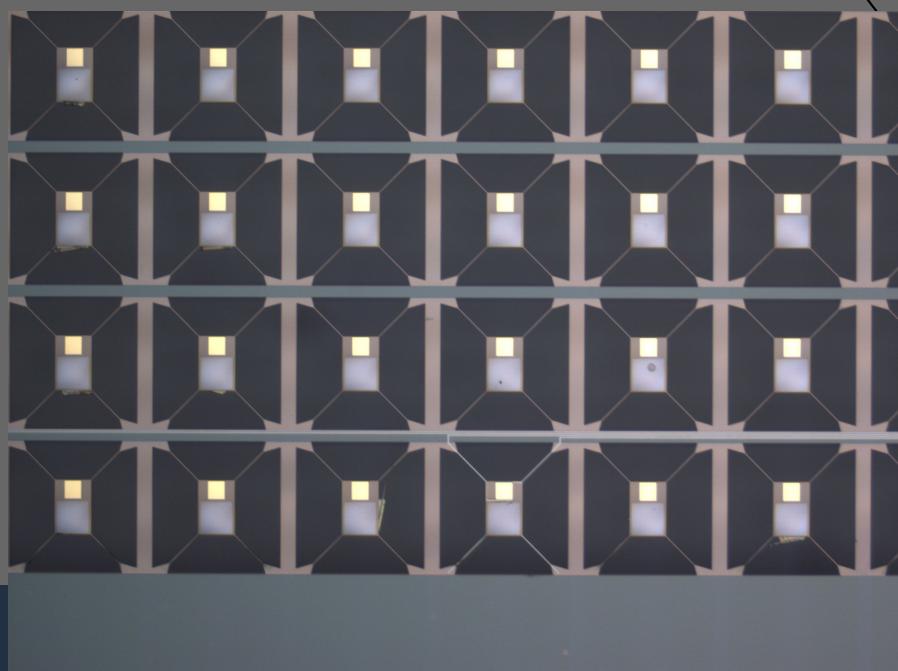

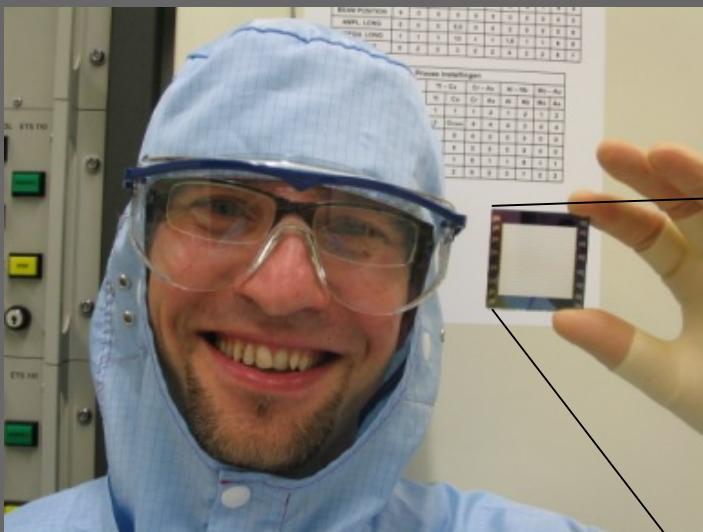

- Radiation breaks pairs
- Broken pairs create signal:
- ΔR : - Semiconductor/STJ
- ΔL : KID (inductance)
- Noise limit: pair creation/annihilation noise
- Not suitable for X-ray > 6eV
- Operates @ $\sim 150\text{mK}$

Thermal detector operation in practice

- Water flow = heat flow = signal
- Water volume = temperature
- Volume is regulated by electro-thermal feedback
- Calorimeter: energy/photon
- Bolometer: power of many photons

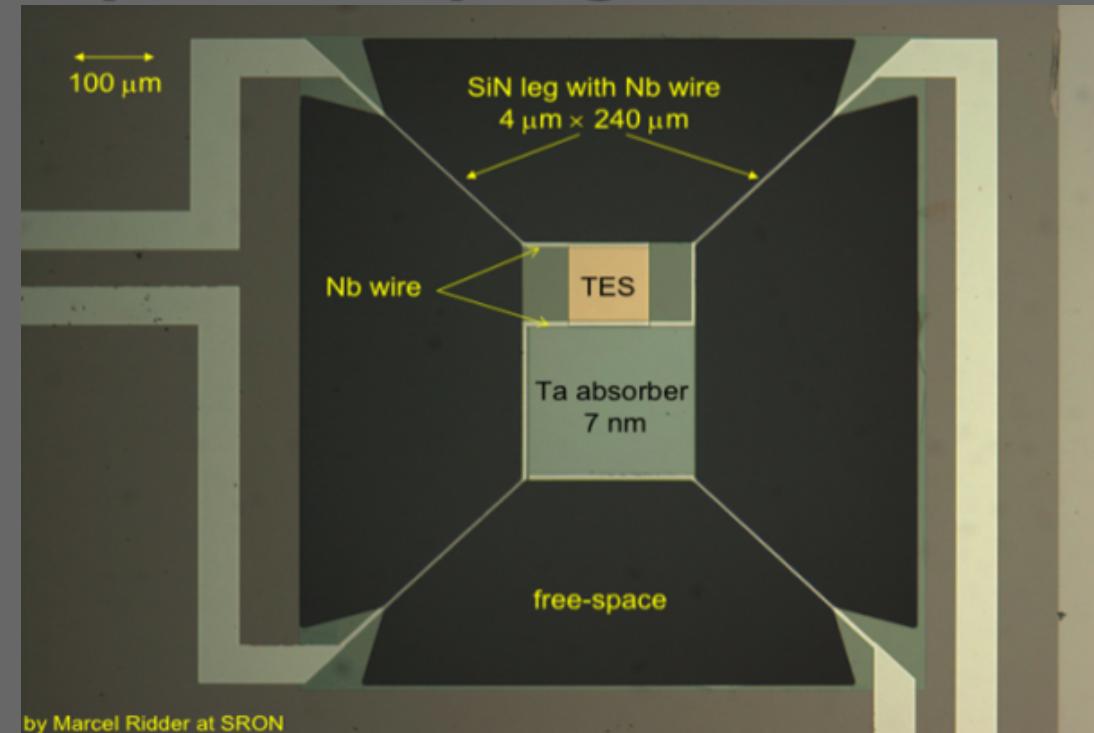

38x38 bolometer array

No wiring to test these devices, just a demo

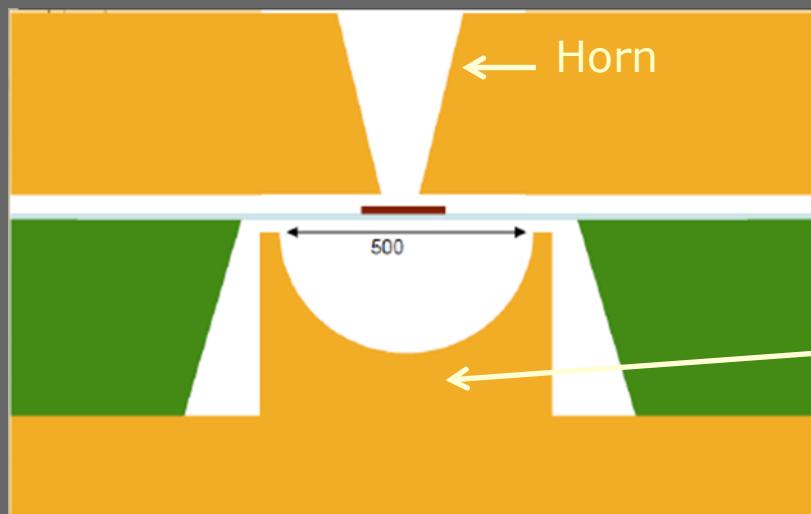

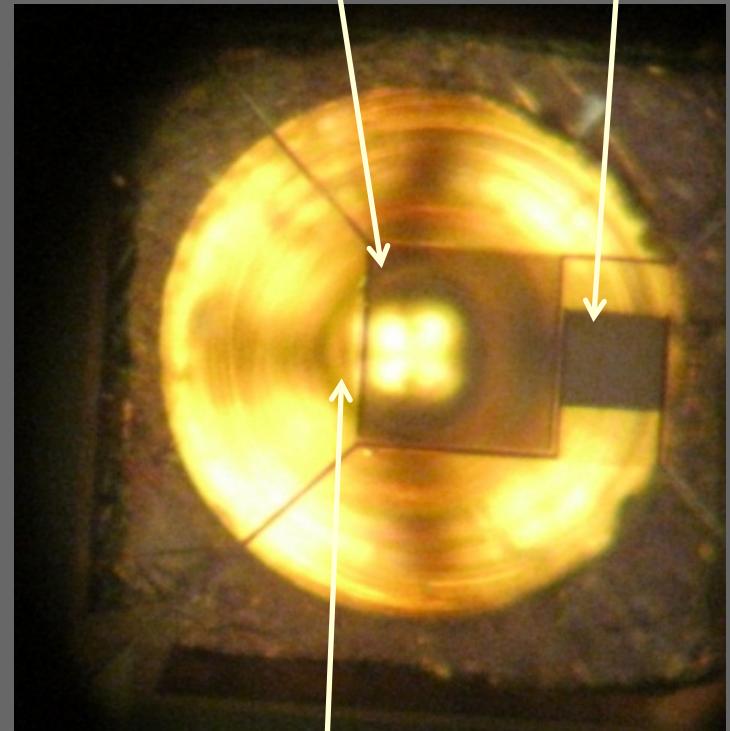

Optical coupling scheme

by Marcel Ridder at SRON

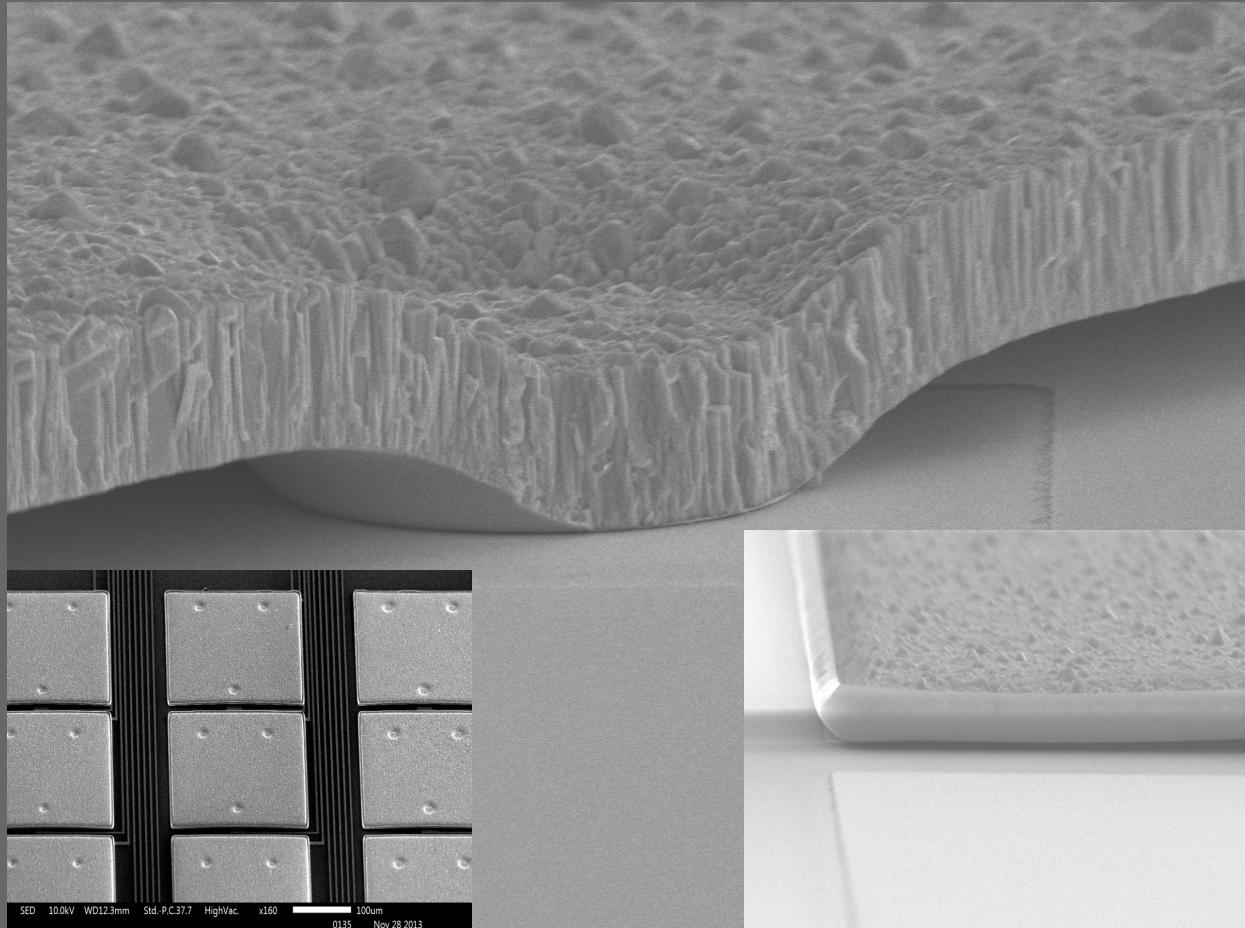

Absorber 200x200 μm

TES

NEP $\sim 5 \cdot 10^{-19} \text{ W}/\sqrt{\text{Hz}}$

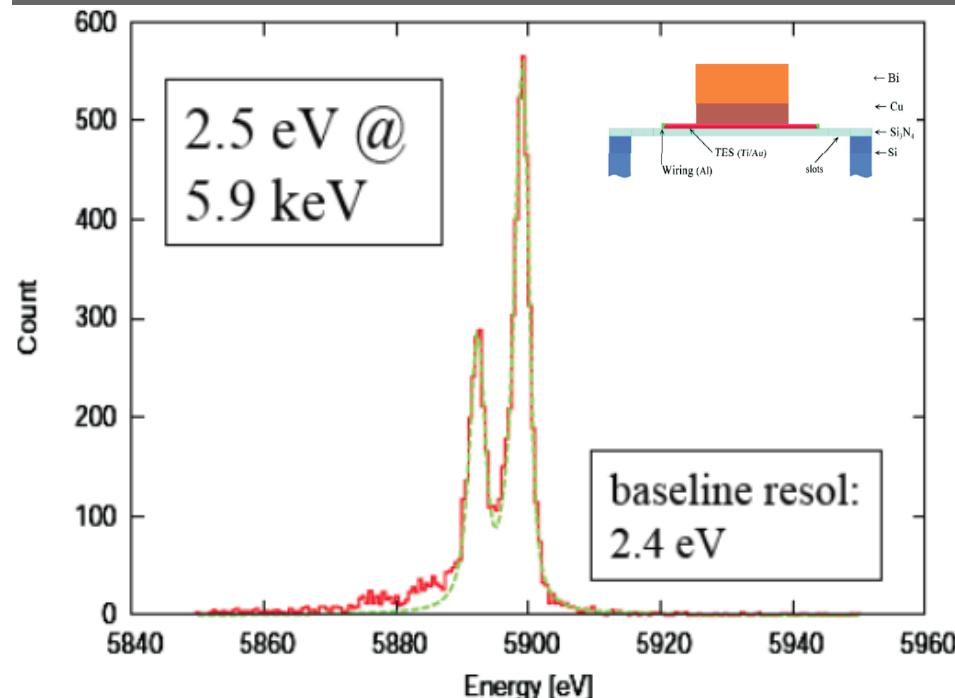

X-ray pixel development

- Development of high-filling factor and high QE pixels array
- 250x250um sputtered Bi on electroplated Au
- TiAu TES with uniform current distribution
- Optimized for the MHz ac-read-out

X-ray pixel performance results

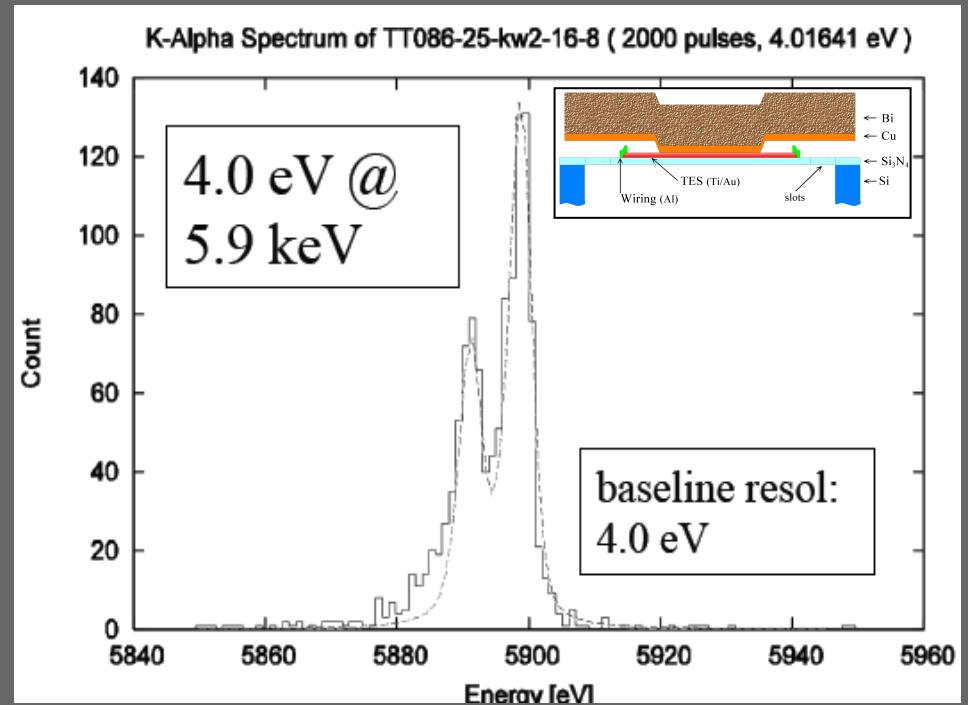

Stopping power 74%, filling factor 20%

TES: TiAuTi
thickness: 20/55/5 nm
size: $150 \times 186 \mu\text{m}^2$

absorber: Cu/Bi
thickness: 1/2.64 μm
size: $100 \times 100 \mu\text{m}^2$

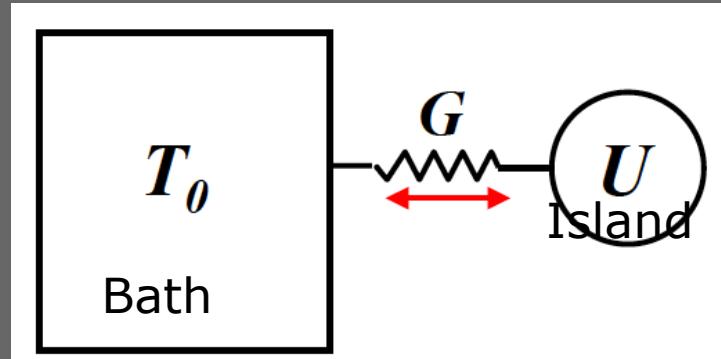

filling factor 92%

TES: TiAuTi
thickness: 20/55/5 nm
size: $146 \times 150 \mu\text{m}^2$

absorber: Cu/Bi
thickness: 0.15/3 μm
size: $240 \times 240 \mu\text{m}^2$

Energy resolution thermal X-ray detectors

Heat capacity vs T:

$$C \propto T^\gamma, \quad \gamma = 1 - 3$$

Number of phonons:

$$N \approx \frac{CT}{k_B T}$$

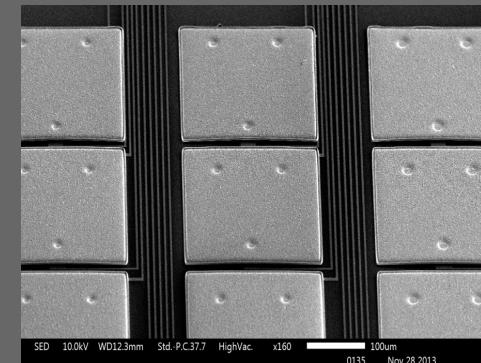

Energy per phonon

$$\Delta U_{rms} = \sqrt{N} \cdot (k_B T) = \sqrt{k_B T^2 C}$$

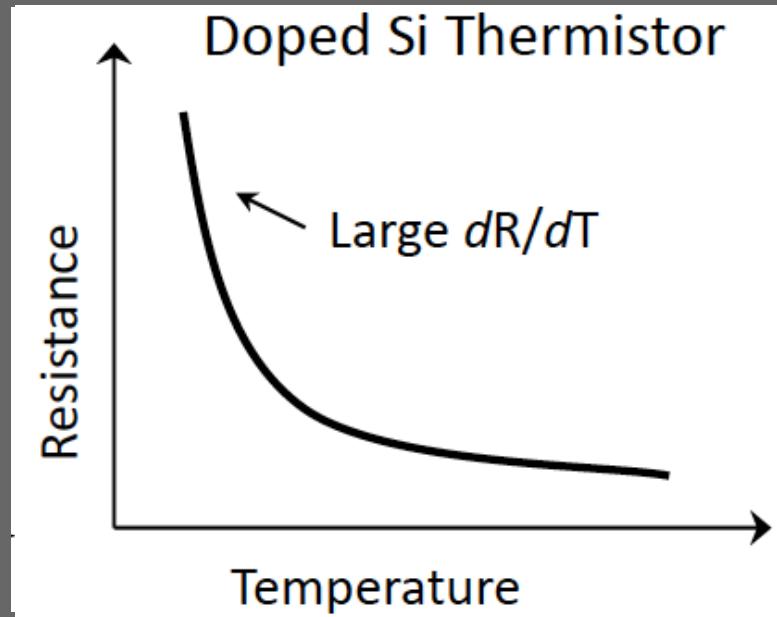

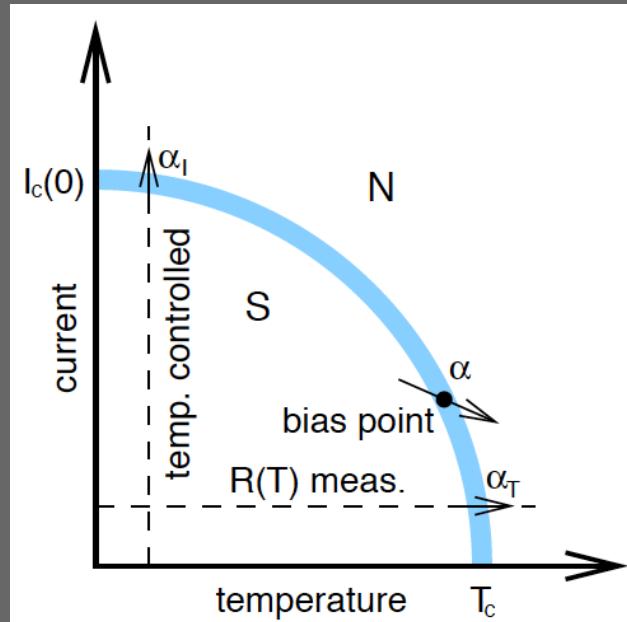

Poisson noise on number of phonons

pixel volume set by pixel size/stopping power =>

\Rightarrow Temperature of $\sim 100\text{mK}$ required for $\Delta E < 3\text{eV}$

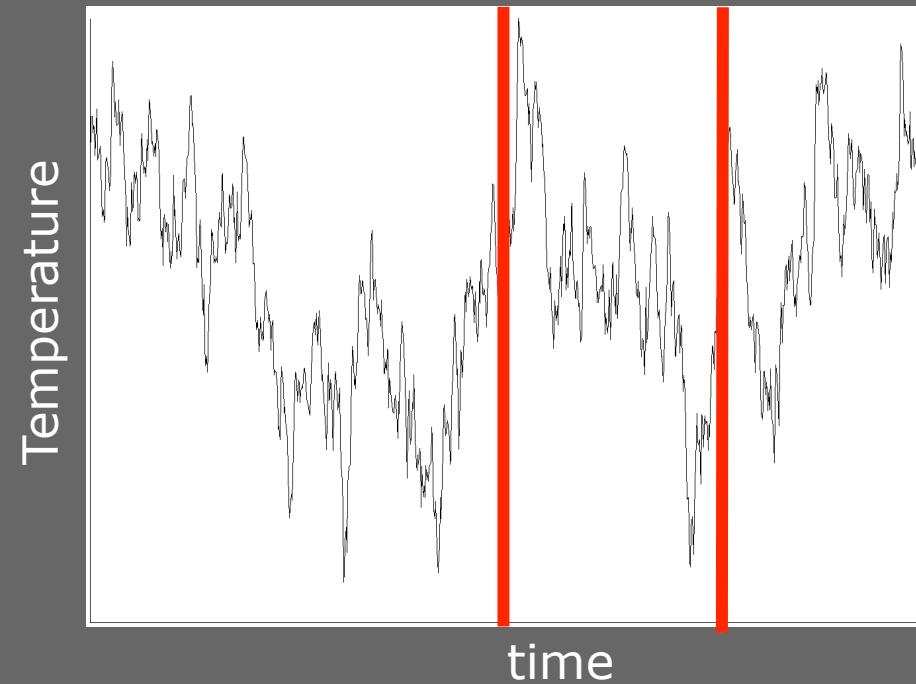

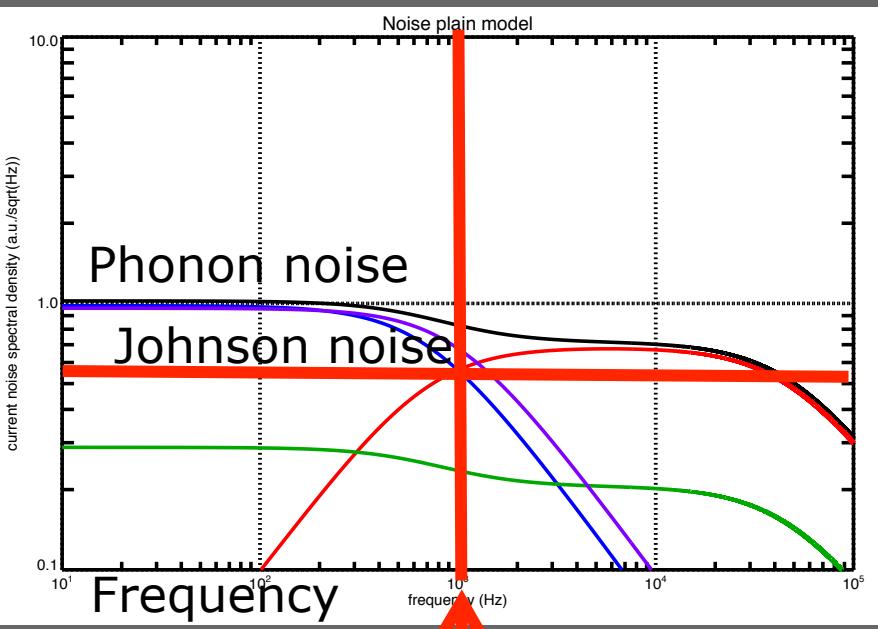

Thermometer sensitivity TES

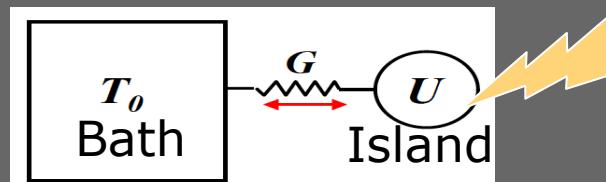

- Superconducting phase transition near T_c
- Strong dependence resistance - temperature
- T_c tuned by proximity effect
- Normalized sensitivity ($\alpha = (dR/R)/(dT/T)$):
 - Si thermistor $\sim \alpha = 1-5$
 - TES $\sim \alpha = 100$

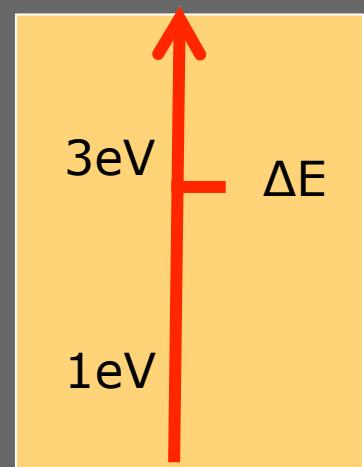

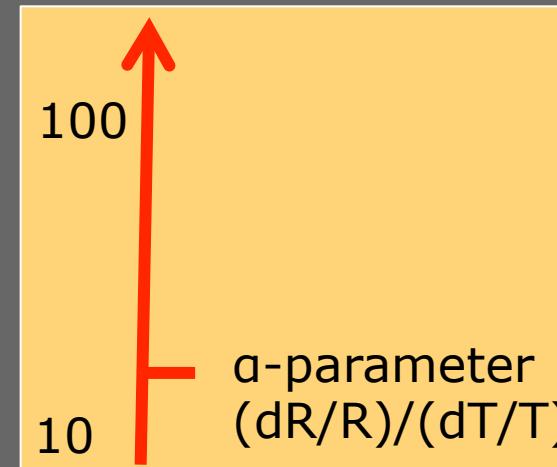

Energy resolution vs thermometer steepness (a)

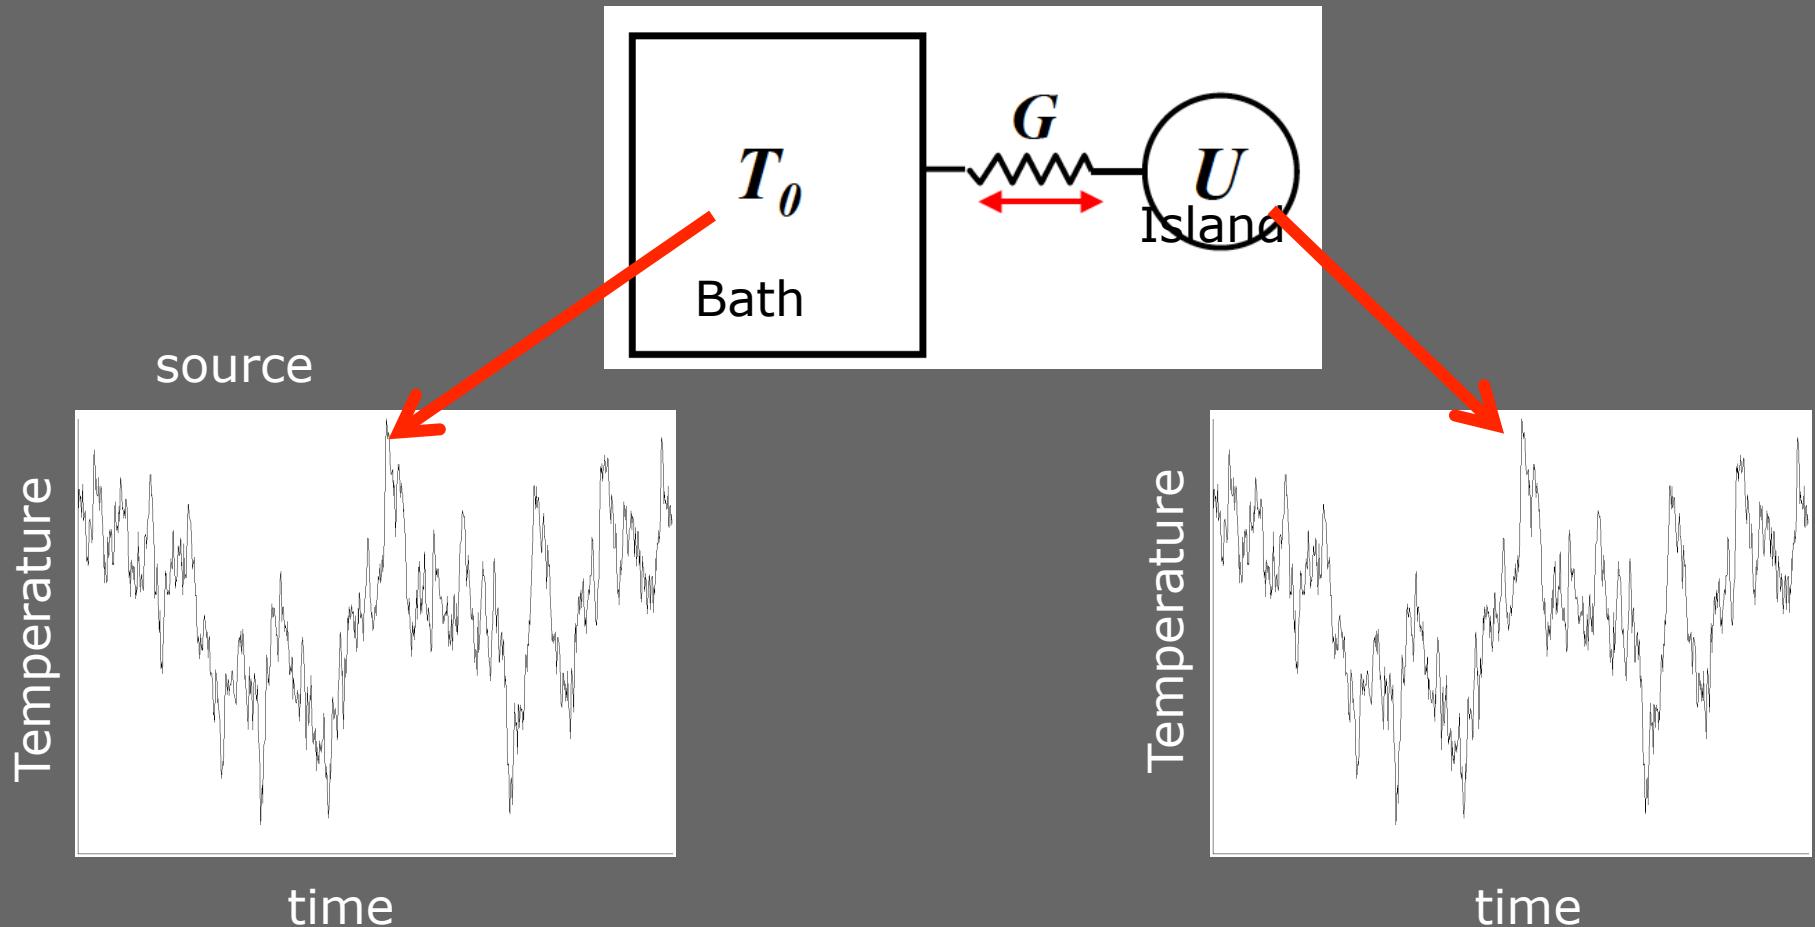

Information bandwidth

- Thermal inertia prevents fast temperature changes over link
- Photon = $\delta(t)$

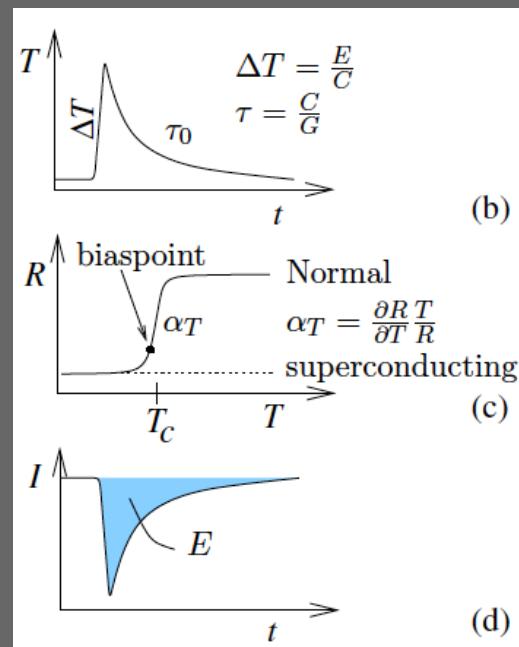

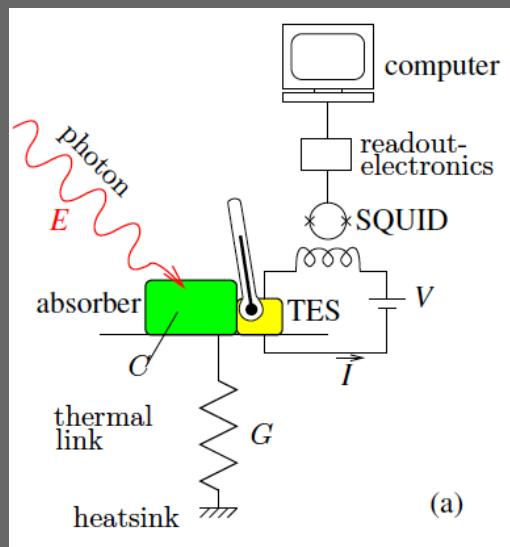

Temperature stability

=> Stability bath \sim stability island (0.3 μK rms)

Electrical readout principle

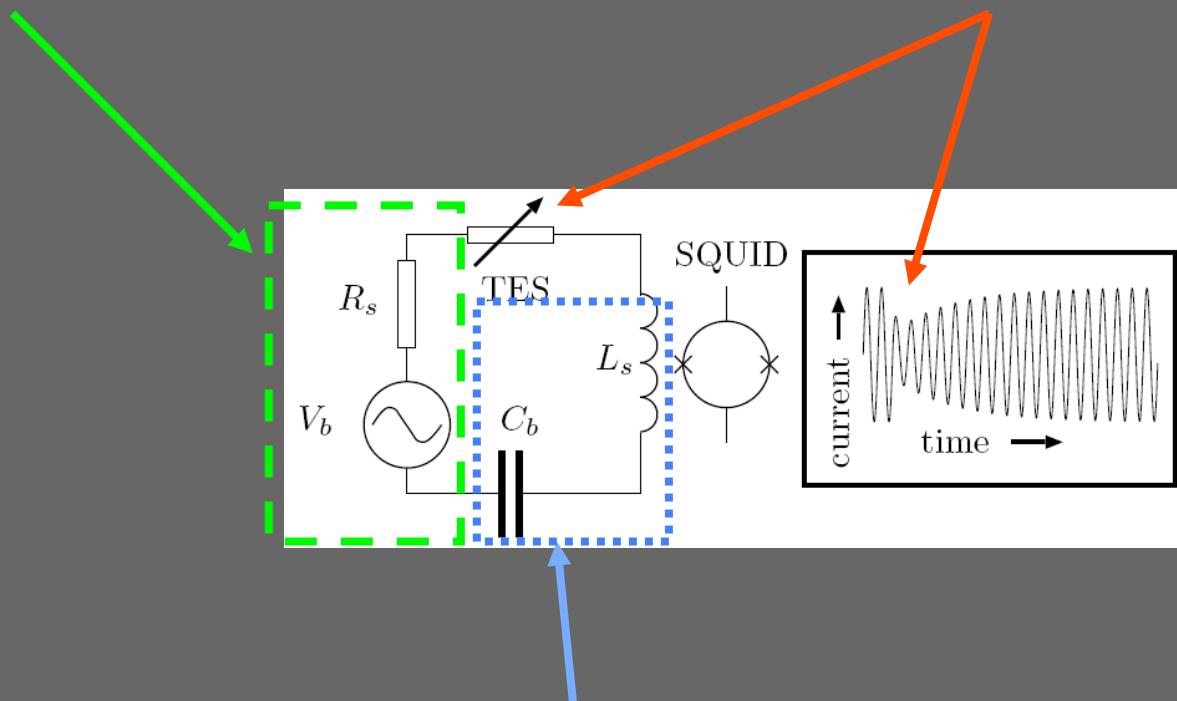

- Voltage biased
- Trans-impedance (current) readout
- SQUIDs as low power amplifiers
- $P_{\text{SQUID}} \sim 1000 * P_{\text{pixel}} \Rightarrow$ multiplexing needed

TES as modulator

- AC voltage bias source produces carrier

Thermal signal
modulates amplitude
of bias current

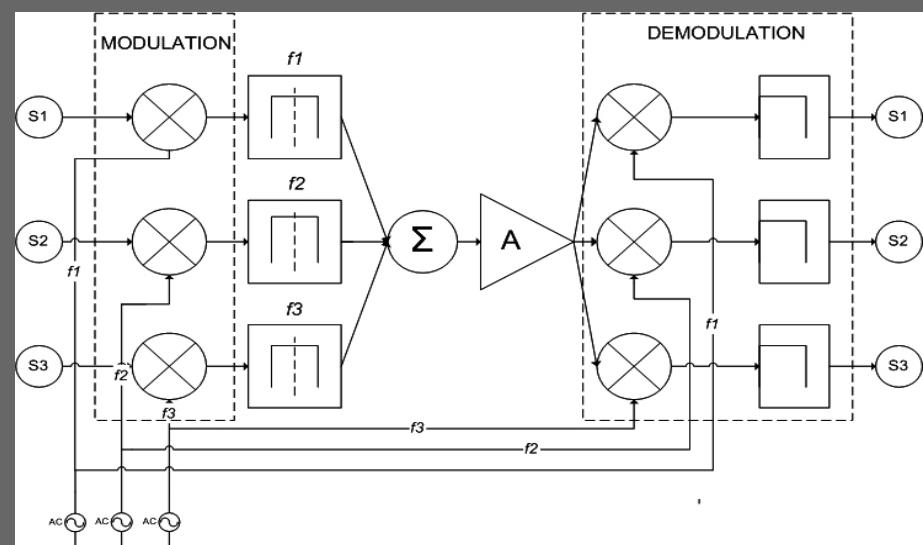

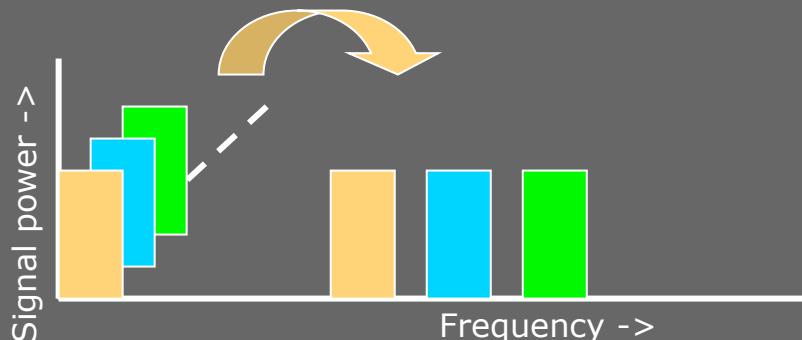

- LC bandpass filter to bandwidth-limit the signal

Multiplexed readout of TESes

- ⇒ Use available bandwidth (10MHz) in SQUIDs -> minimization of wires/dissipation
 - No signal loss allowed
 - => Use Modulation: shift in frequency space by multiplication with carrier
 - => thermal signals become independent
 - Voltage source as carrier generator
 - TES as amplitude modulator
 - LC bandpass filter to separate signals ($Q \sim 10^4$)
 - SQUID in summing point

Modulation: separation in frequency space

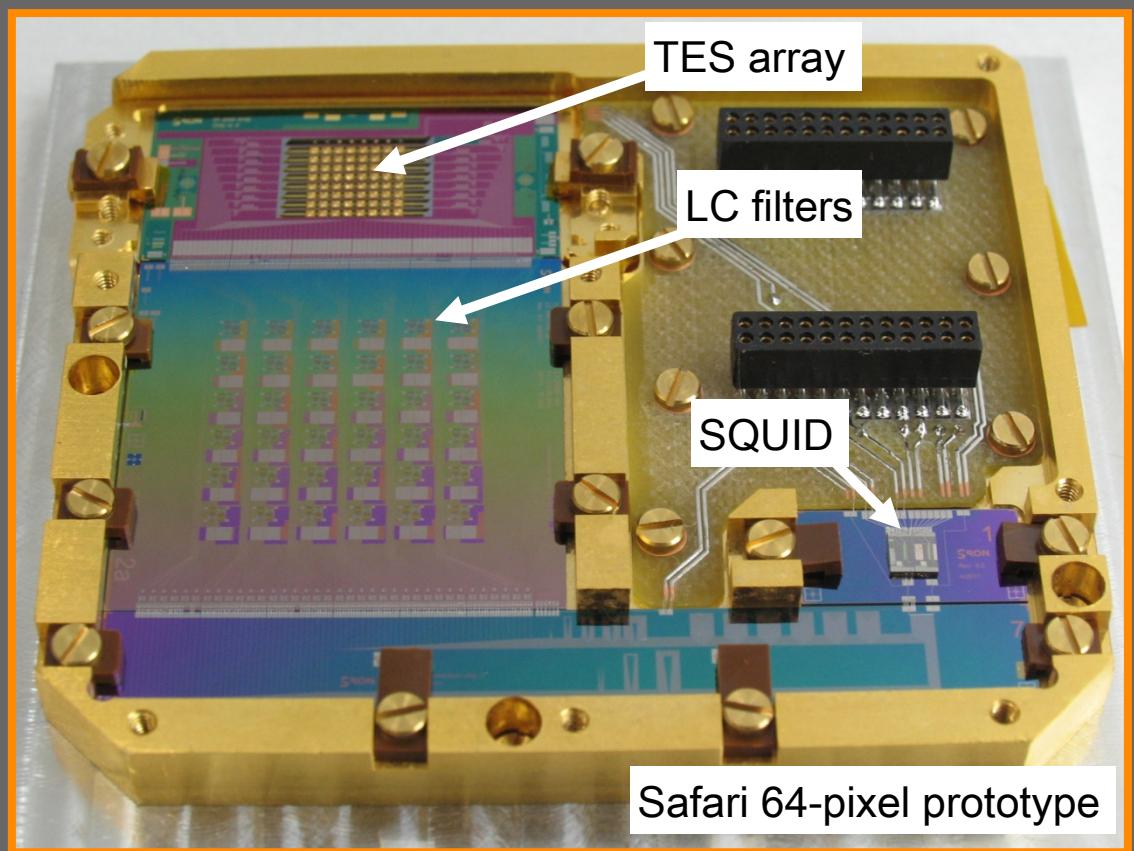

Planar FDM demonstrator

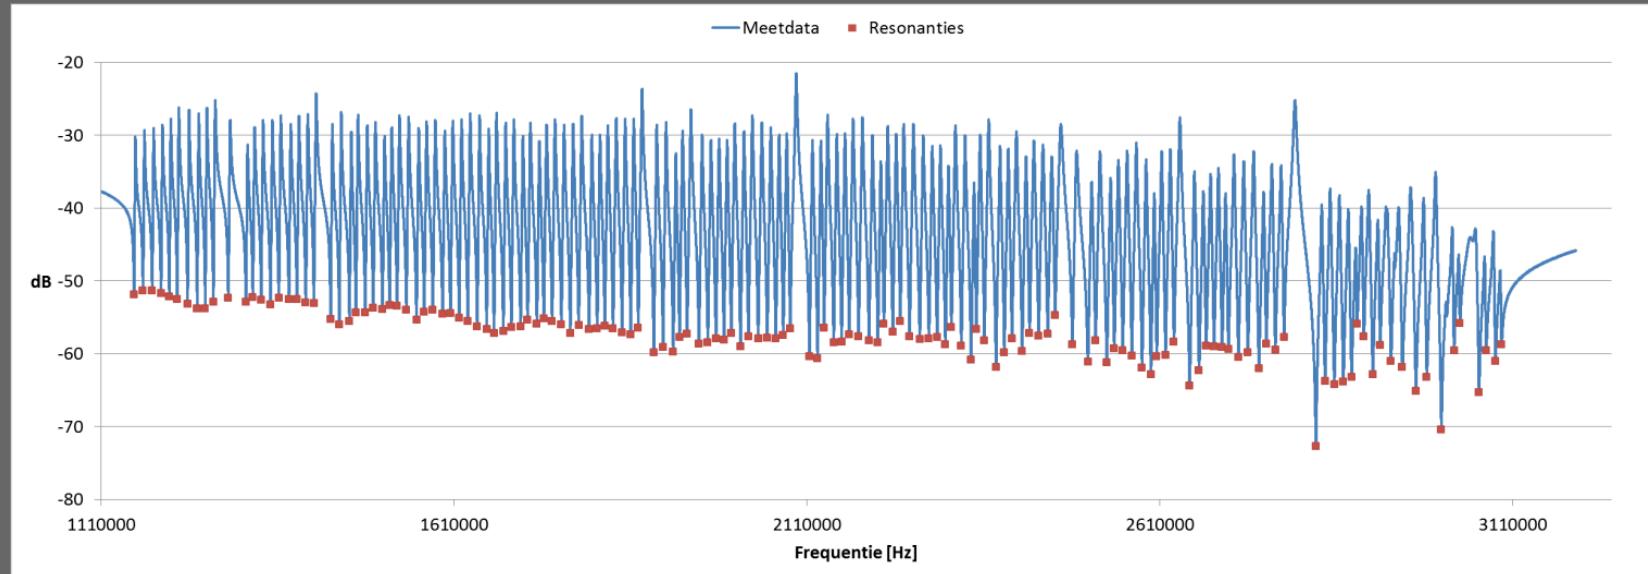

- Light-tight box
- 72 channel LC filter
- Bolometer array
- Digital demodulation

Mux factor:

- 160 pix/channel for infrared
- 40 pixel/channel for Xray

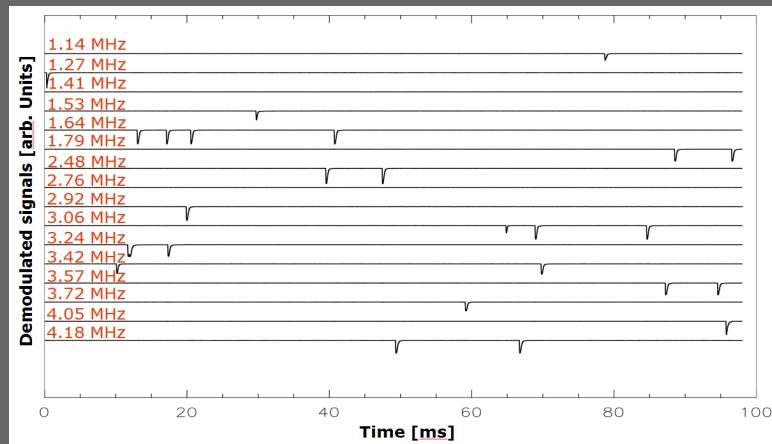

160 resonators for one channel

- Efficient use of bandwidth
- Low power dissipation

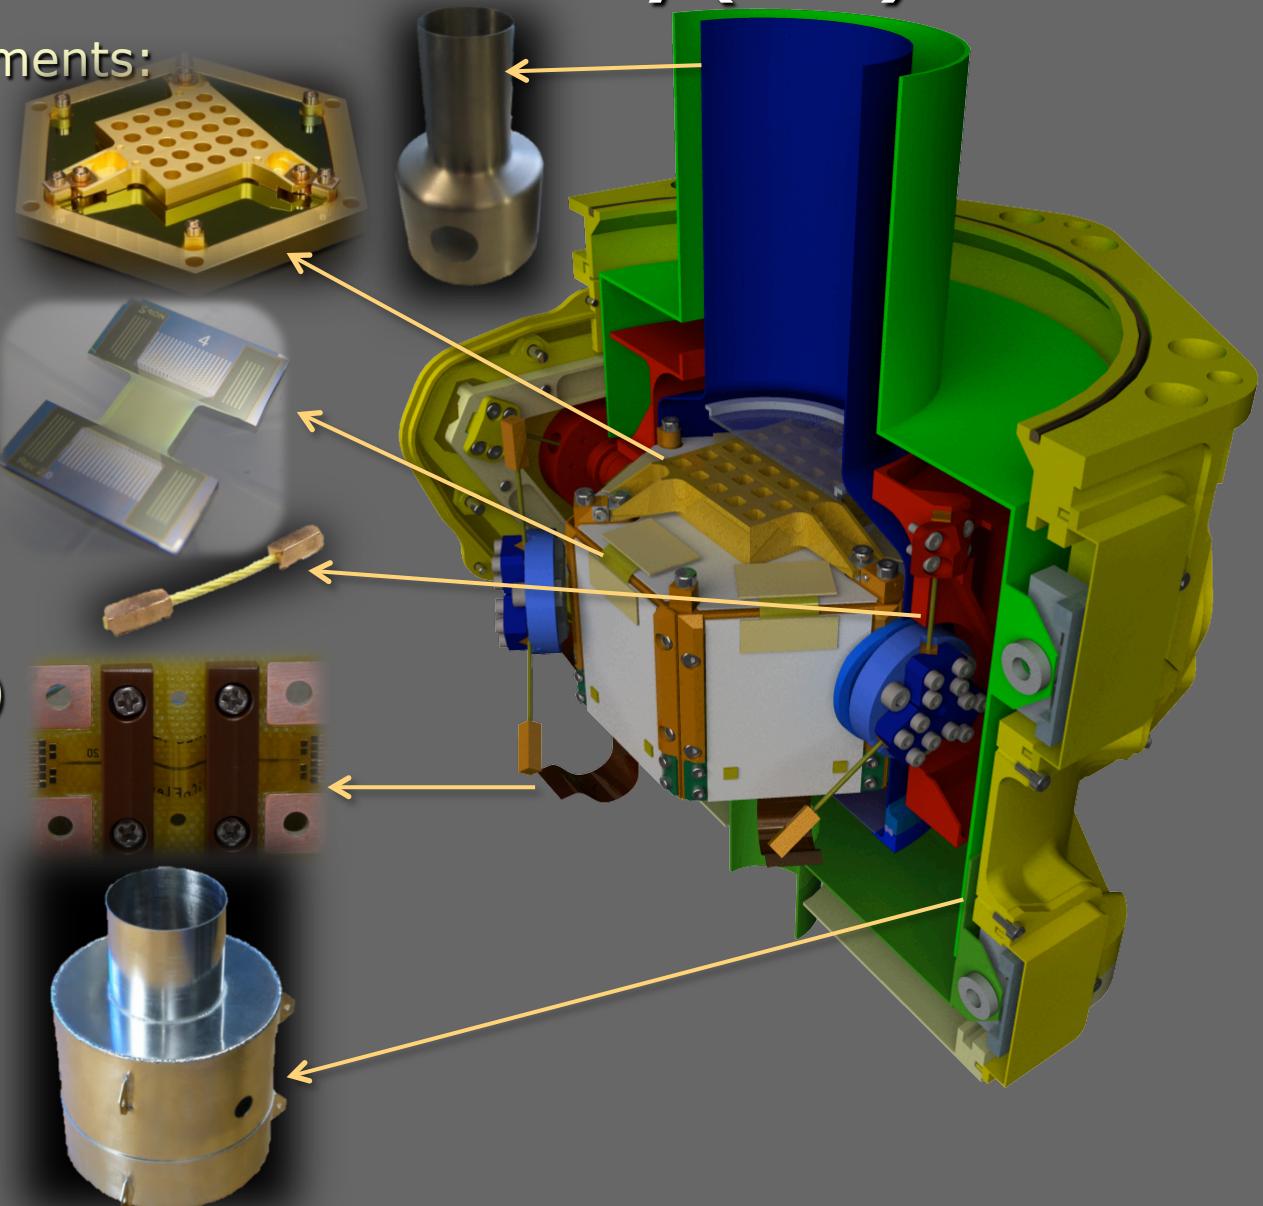

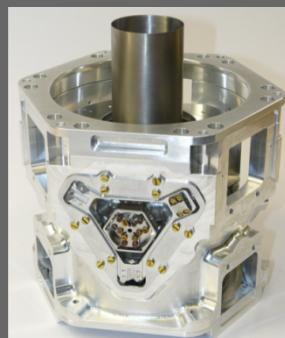

SQUID amplifier: 50 – 100 nW/pixel@4K
(KIDs) 1 μW/pixel @4K

TES detector Focal Plane Assembly (FPA)

FPA technology developments:

- Interconnects
- Detector mounting
- Kevlar thermal insulating suspension
- Magnetic shielding:
 - Niobium (superconducting)
 - Cryoperm 10

Summary

- Next generation space telescopes require very sensitive detectors
- Cryogenic detectors can provide the required performance
- Fundamental thermodynamic laws dictate the use of very low temperatures

Thank you
