Hunting for dark matter

DARK MATTER
?

DARK MATTER is the name given to material in the Universe that does not emit or reflect light but is necessary to explain observed gravitational effects in galaxies and stars. Dark matter, along with dark energy, totals 96% of the Universe, yet it remains a mystery as to what exactly it is.

Acrylic felt, wool felt, and fleece with gravel fill for maximum mass.

Packaged in a black opaque bag designed for concealing contents.

The PARTICLE ZOO

Outline

How do cosmologists provide better models for dark matter experiments?

Velocity distribution of dark matter

Relevant for direct detection

[See YYM+ (ApJ 2013) [1210.2721](#) and YYM+ (PRD 2013) [1304.6401](#)]

Dark matter subhalo abundance

Relevant for indirect detection and astrophysical observations

[See YYM+ [1503.02637](#)]

Results are based on dissipationless CDM N-body simulations.

Dark Matter Velocity Distribution

aka
astrophysical input

Velocity Distribution Function (VDF) in direct detection

- The differential event rate of the DM-nucleon collision depends on the Galactic **Velocity Distribution Function (VDF)**.

$$\begin{aligned} \left. \frac{dR}{dQ} \right|_Q &= \frac{\rho_0}{m_{\text{dm}} m_N} \int_{v_{\text{min}}(Q)} d^3v v f(\mathbf{v} + \mathbf{v}_e) \frac{d\sigma}{dQ} \\ &= \frac{\rho_0 \sigma_0}{2\mu^2 m_{\text{dm}}} A^2 |F(Q)|^2 \int_{v_{\text{min}}(Q)} d^3v \frac{f(\mathbf{v} + \mathbf{v}_e)}{v} \end{aligned}$$

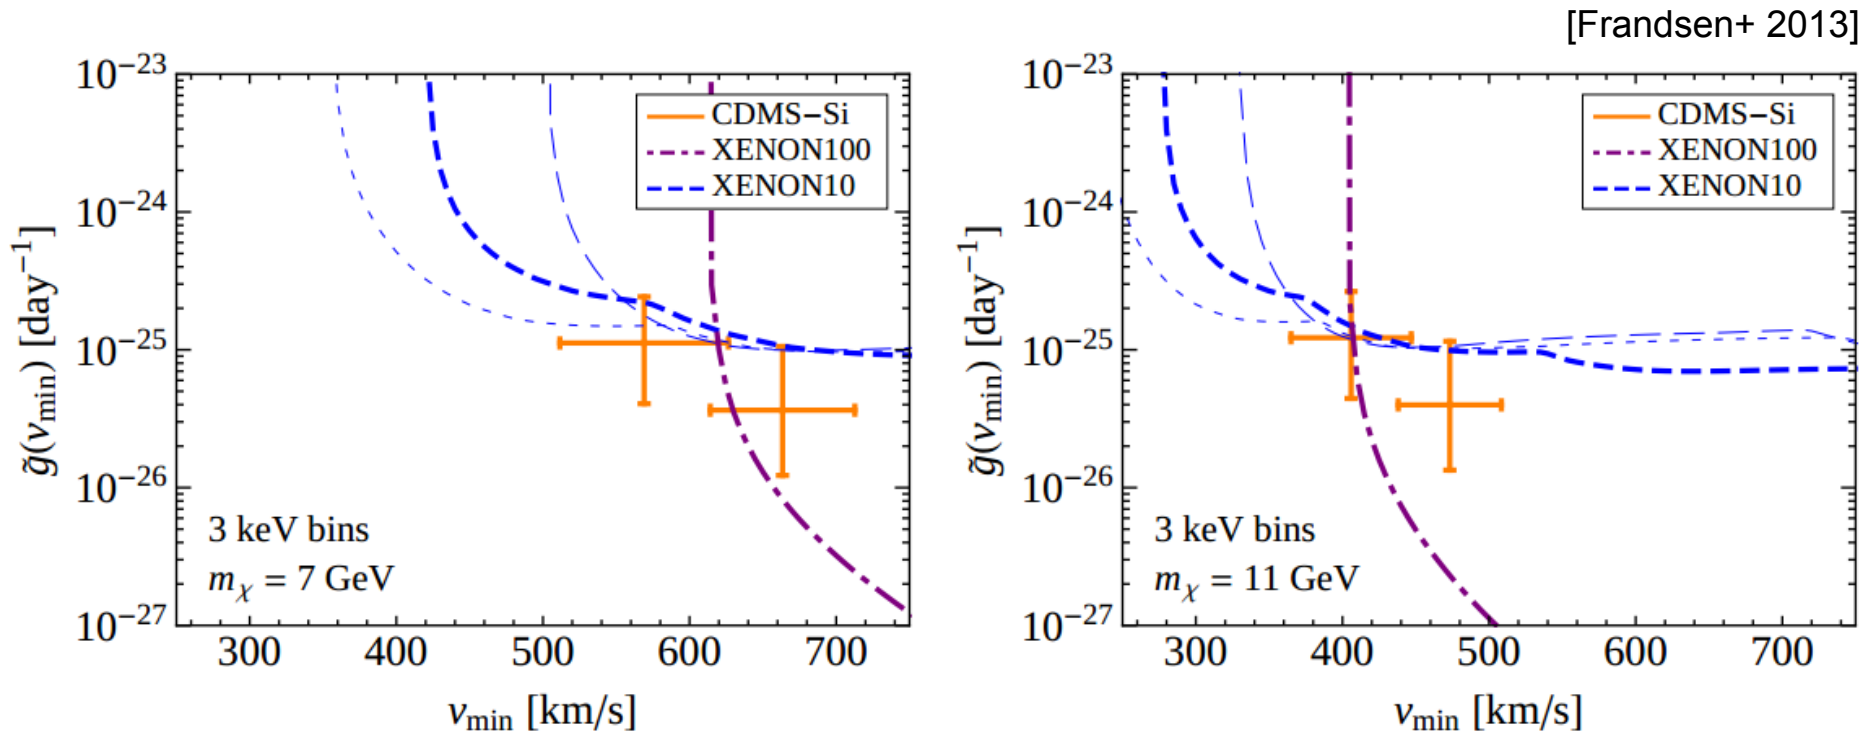

- The relevant quantity:

The $g(v_{\min})$ method

Fox+, PRD (2011)
Frandsen+, JCAP (2012)

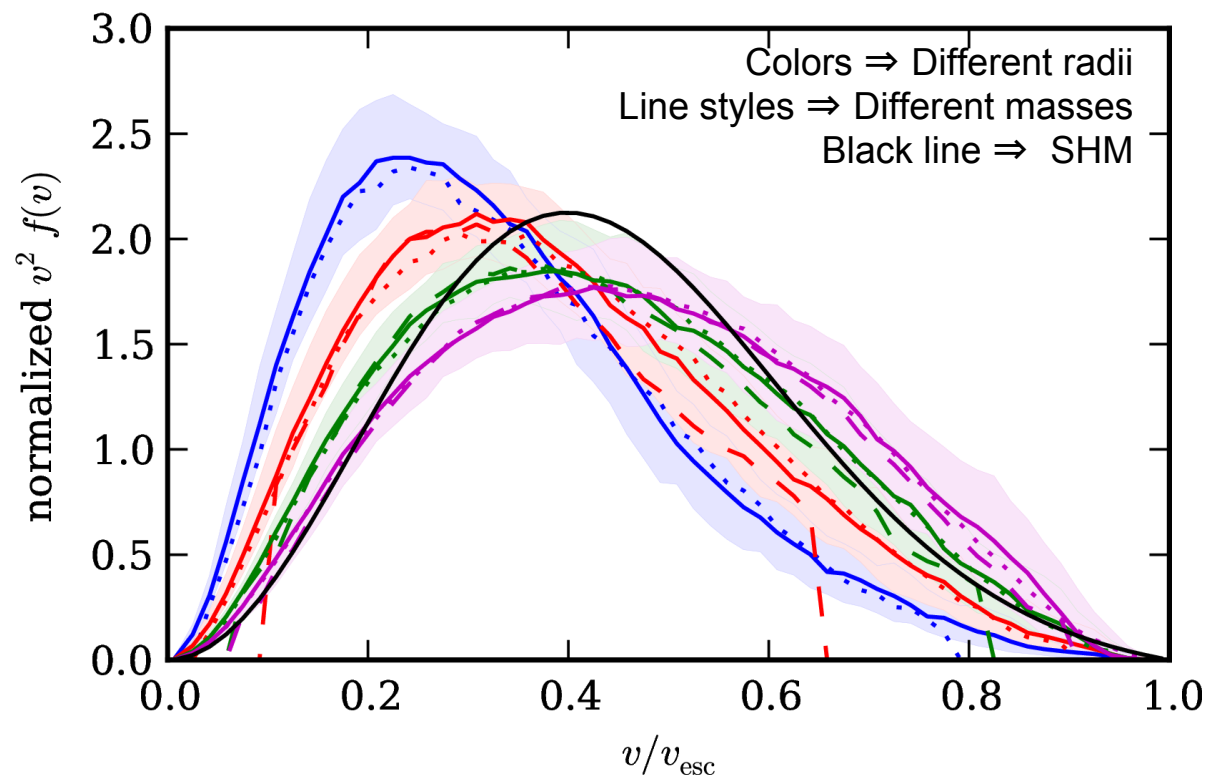

Instead of comparing experimental results in the plane of cross section vs. WIMP mass, compare the results in the plane of $g(v_{\min})$ and v_{\min} , with a WIMP mass assumed.

"Standard Halo Model"

$$f(v) \propto \exp\left(-\frac{v^2}{v_0^2}\right)$$

- Maxwell-Boltzmann distribution + unphysical cutoff.
- The parameter v_0 is determined by the circular velocity.
- There's no physical reason for the DM VDF to be like a M-B distribution.

Why doesn't DM follow the Maxwell-Boltzmann distribution ?

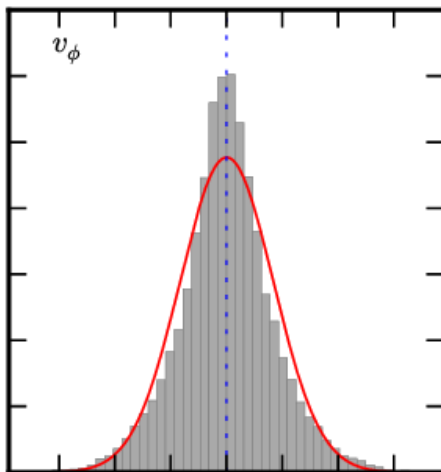

$v=0$

Is the **equilibrium** state really isotropic?

Even if the anisotropy parameter is zero, there still exists anisotropy in the velocity space.

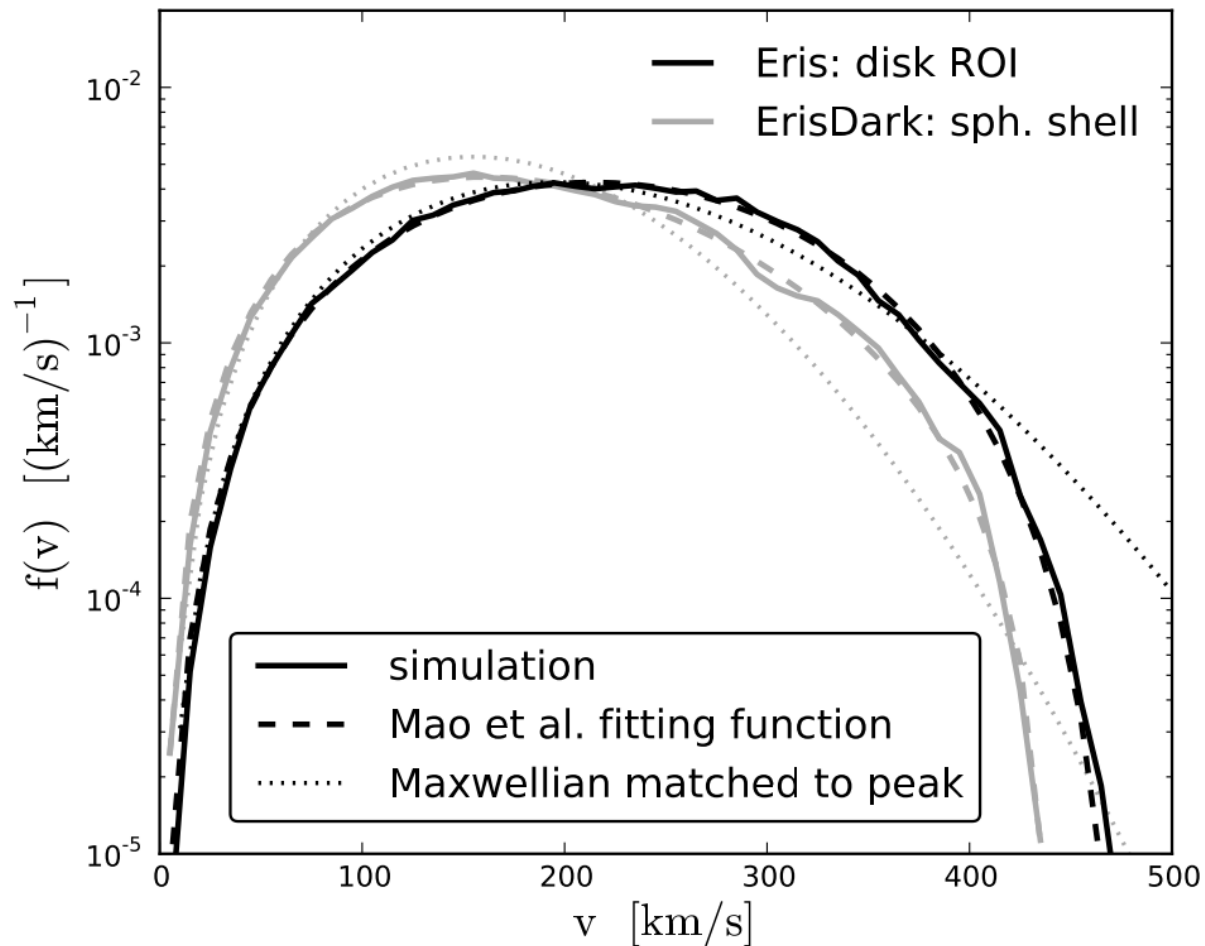

An accurate model of VDF

$$f(v) \propto \exp\left(-\frac{v}{v_0}\right) (v_{\text{esc}}^2 - v^2)^p, \quad v \in [0, v_{\text{esc}}]$$

- Two parameters: v_0 and p
 - **NOT** a variant of a Maxwell-Boltzmann distribution (eg. Standard Halo Model)
 - Based on an **exponential distribution** (flattened shape): could be due to the **velocity anisotropy** (ellipsoid)
 - Tail modified by a **power-law cutoff** in energy
-

Comparing VDF models with DM-only simulation.

Comparing VDF models with hydro simulation.

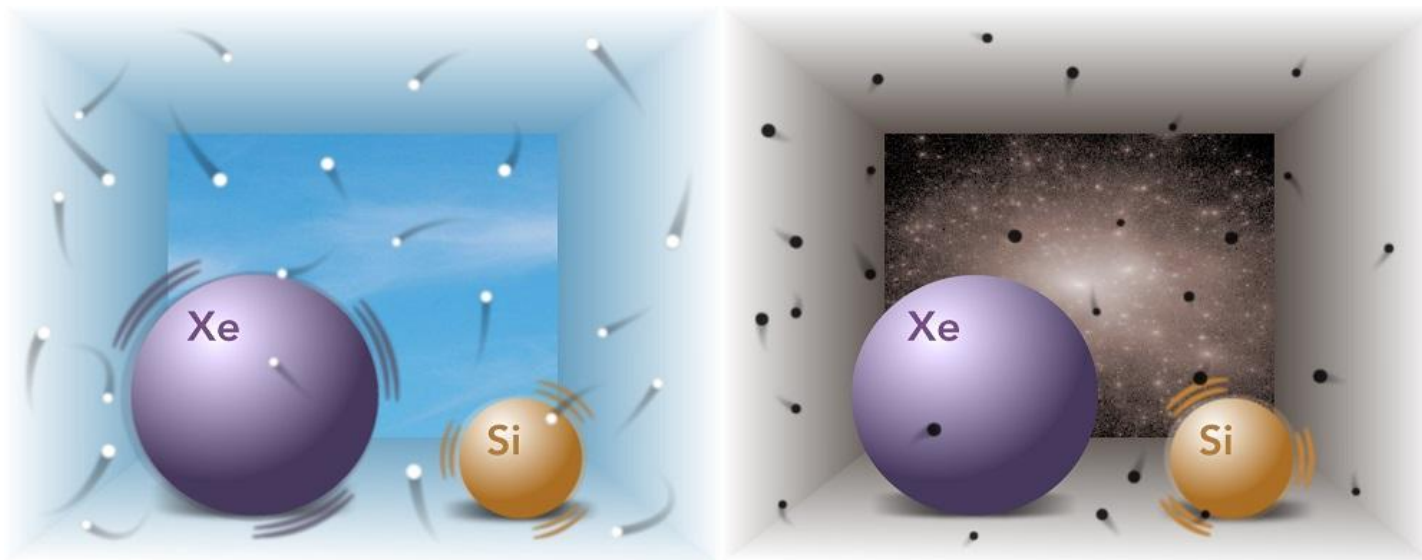

[Kuhlen+ 2013]

Does the VDF really matter for experiments?

Yes, especially for larger v_{\min}

(light WIMP, heavy target, high recoil energy)

$$v_{\min} = \sqrt{\frac{E_{nr} m_n}{2\mu^2}}$$

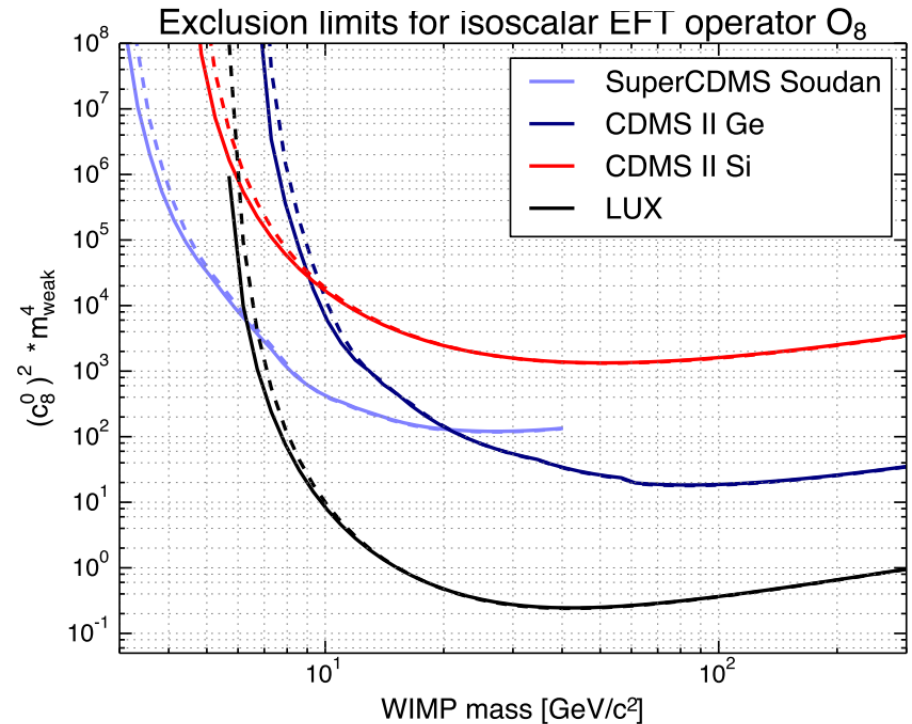

[Greg Stewart/SLAC National Accelerator Laboratory]

Does the VDF really matter for experiments?

Yes, especially for larger v_{\min}
 (light WIMP, heavy target, high recoil energy)

$$v_{\min} = \sqrt{\frac{E_{nr} m_n}{2\mu^2}}$$

[Schneck+ (SuperCDMS Collab.) 2015]

Prior distributions of VDF parameters

Quantify the impact of VDF on the energy spectrum

The relative scatter (range)
of $g(v_{\min})$ for:

v_{rms} in [0.38, 0.48] ($p = 1.5$)

v_{rms} in [0.42, 0.44] ($p = 1.5$)

p in [0, 3] ($v_{\text{rms}} = 0.43$)

v_{rms} \Rightarrow the overall shape

p \Rightarrow detailed shape and
the asymptotic tail

$$g(v_{\min}, \mathbf{v}_e) \equiv \int_{v_{\min}} d^3v \frac{f(\mathbf{v} + \mathbf{v}_e)}{v}$$

Half-time summary

- We propose a flexible, parameterized VDF model, along with the priors on the parameters, based on cosmological simulations.
 - Future experiments should include the VDF in the analysis, preferably by marginalizing over the VDF parameters.
 - When *real* DM signals start to be found in direct detection experiments, realistic VDF models can provide insights to the properties of the MW halo.
 - The mechanism of non-Maxwellian VDF and its relation to the equilibrium state of the DM halos are still unclear and need to be understood theoretically.
-

MY LOVE
for you is like
dark matter:

Still haven't
found it.

MY LOVE
for you is like
dark matter:

You can't see it
but it's
ALWAYS THERE.

What are subhalo abundance functions and what do we know about them?

Aquarius [Springel+ 2008]

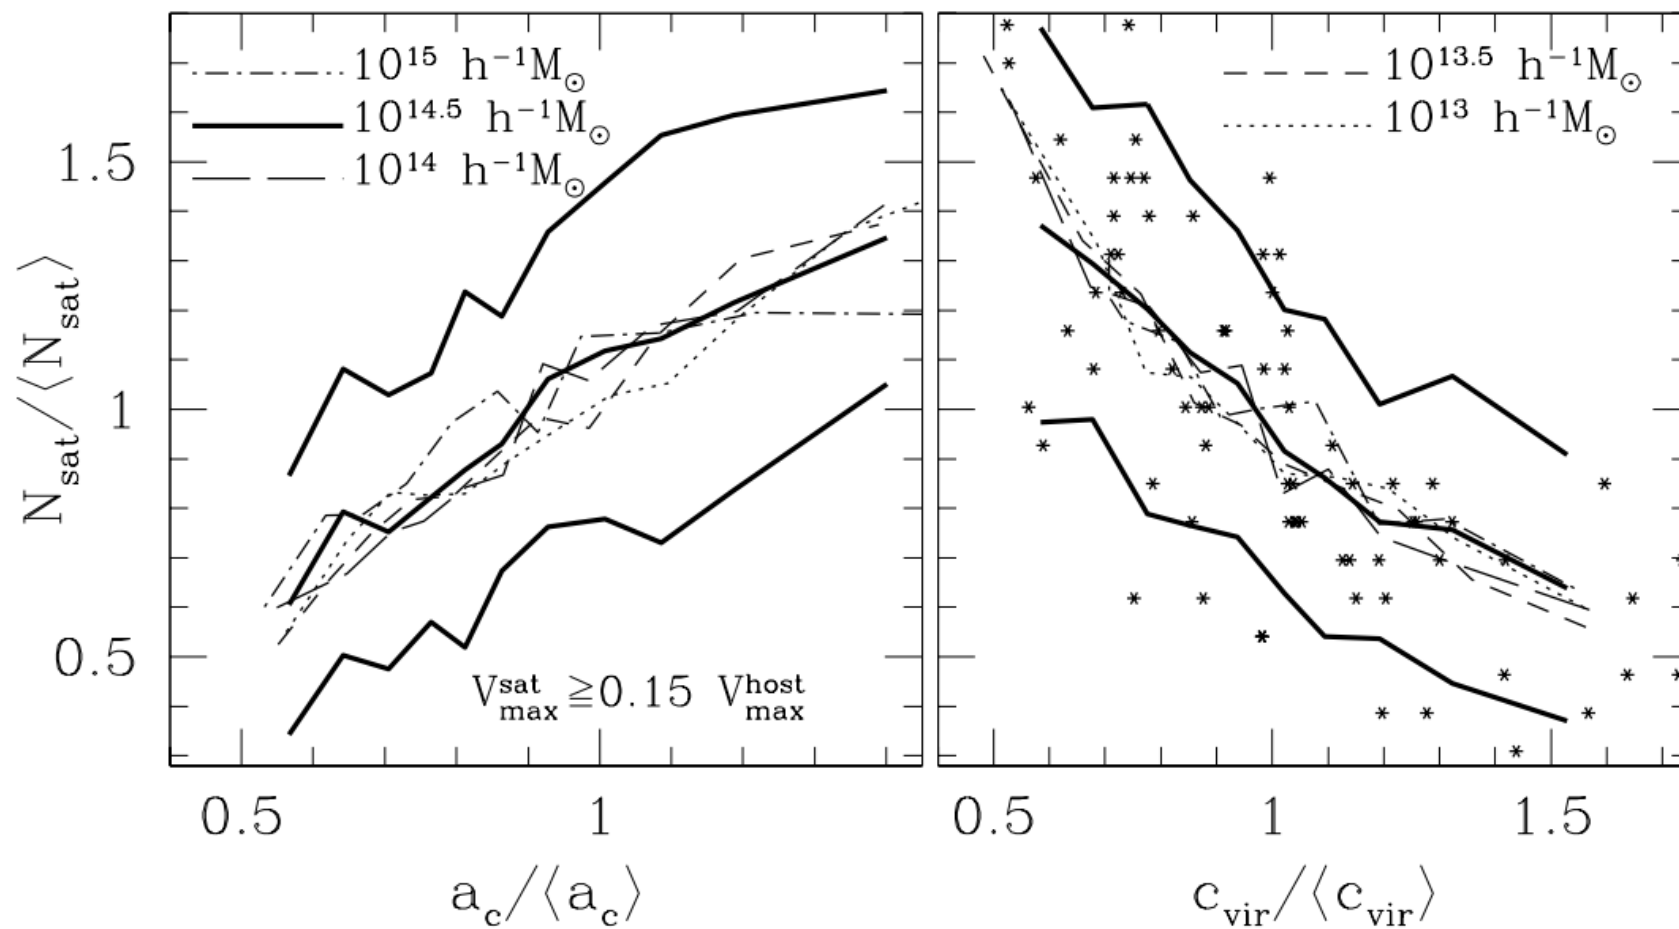

ELVIS [Garrison-Kimmel+ 2014]

The halo-to-halo scatter?

The scatter in subhalo occupation at a fixed halo mass is **larger** than Poisson scatter.

[Boylan-Kolchin+ 2010]

Correlation between subhalo abundance and halo formation time/concentration

[Zentner+ 2005]

How to model the subhalo abundance function and its halo-to-halo scatter?

Zoom-in simulations of Milky Way-like halos

- mass resolution $\sim 3 \times 10^5 M_{\text{sun}}$
- subhalo resolved down to 8 km/s

How to model the subhalo abundance function and its halo-to-halo scatter?

1. Halo-to-halo scatter affects mostly the normalization of the SAF
 2. Normalization and host concentration are (anti-)correlated
 3. The power-law index is constant (at least in a narrow mass bin)
-

Poisson Point Process (PPP) for a single halo

Re-simulate one single host halo with different small-scale modes.

An accurate subhalo abundance model

$$\langle N(v) \rangle = \left(\frac{v}{v_0} \right)^n - \left(\frac{v_{\text{cut}}}{v_0} \right)^n$$

$$v_0 = a v_{\text{vir}} \quad v_{\text{cut}} = b v_{\text{vir}} \quad n = n_0$$

$$a := a_0 \left(\frac{v_{\text{max}}}{v_{\text{vir}}} \right)^\alpha$$

$$b := b_0 \left(\frac{v_{\text{max}}}{v_{\text{vir}}} \right)^\beta$$

Is the power-law index constant?

$$n = -3.05 \nu(M, z)^{-0.1} \quad \nu(M, z) = \frac{\delta_c}{\sigma(M)D(z)}$$

Possible mass/redshift-dependence of the power-law index

Summary

1. Scatter in subhalo abundance = halo-to-halo scatter in the sample + Poisson scatter for each individual halo
2. Halo-to-halo scatter comes from scatter in halo mass and concentration

The model can successfully reproduce the mean and the scatter of subhalo occupation in simulations.

It also provides a convenient method to sample a sequence of v_{\max} that represents the subhalos of a given host halo.

Halo mass and concentration characterize subhalo abundance. Knowing the prior of MW concentration is essential for statistical analysis.

Final take-home messages

How do cosmologists provide better models for dark matter experiments?

Velocity distribution of dark matter

Relevant for direct detection

[See YYM+ (ApJ 2013) [1210.2721](#)
and YYM+ (PRD 2013) [1304.6401](#)]

Realistic VDF models (ie. *not* standard halo model) are needed for accurate analysis and for extracting info of MW halos.

Dark matter subhalo abundance

Relevant for indirect detection and astrophysical observations

[See YYM+ [1503.02637](#)]

High-concentration halos have fewer subhalos. This model can predict the expected number of subhalos and its scatter.

Results are based on dissipationless CDM N-body simulations.
