

xAOD MET Trigger Study

Muhammad Firdaus Mohd Soberi

March 26th 2015

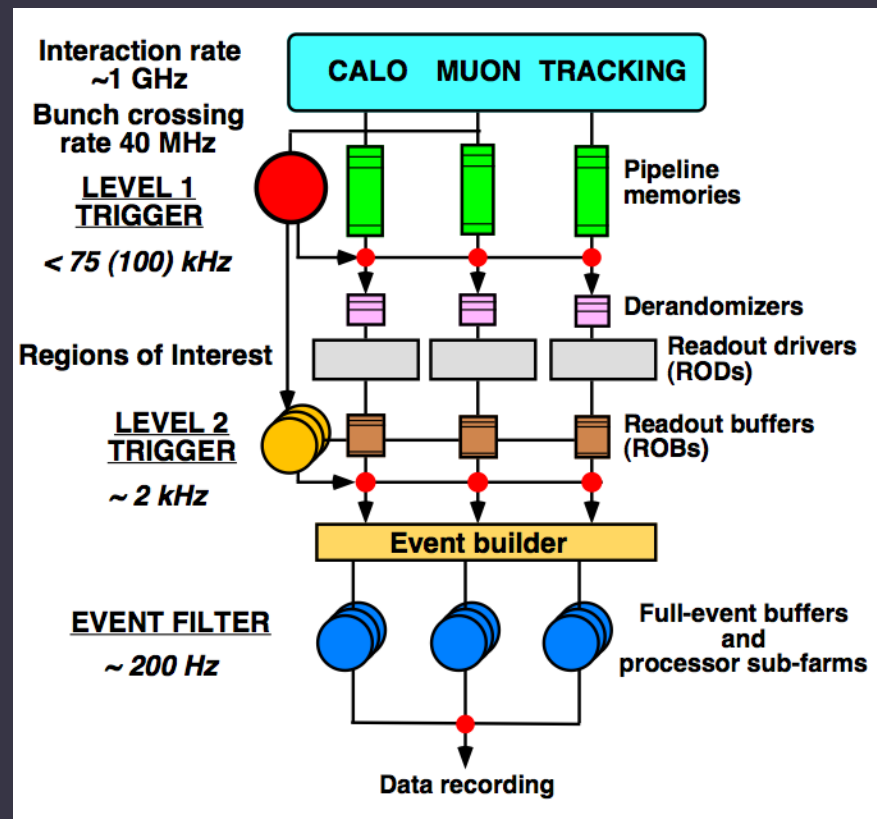

On behalf of CERN-Umichigan REU Meeting #2

Overview

- ▶ Trigger and offline MET
- ▶ How it affect each other (offline vs online)
- ▶ What can we improve

ATLAS Trigger System (3 level Trigger)

Different Trigger Level

- ▶ L1
- ▶ HLT (High Level Trigger)
 - ▶ In Run1 includes L2 and EF
 - ▶ In Run2 includes EF
- ▶ LVL1 decision based on coarse granularity calo towers and muon trigger stations
- ▶ LVL2 can get data at full granularity and combine info from all detectors. Emphasis on fast rejection. Region of interest from LVL1 used to reduce data requested to few % of full event.
- ▶ EF refines selection according to LVL2 classification, performing fuller reconstruction.
- ▶ Peak luminosity Run2 $2 \times 10^{34} \text{cm}^{-2} \text{s}^{-1}$
- ▶ Planned luminosity initially $0.5 \times 10^{34} \text{cm}^{-2} \text{s}^{-1}$

MET Trigger Study

- ▶ See the effect of trigger on offline MET
- ▶ Study the 'turn on' curve for MET and efficiency plots
- ▶ Use different analysis type as test of the trigger implementation
- ▶ (MonoHiggs, Ttbar, ZnuuHbb)

Efficiency Plots (as function of offline MET)

- ▶ L1_XE50
- ▶ L1_XE70
- ▶ HLT_xe60
- ▶ HLT_xe70
- ▶ HLT_xe100
- ▶ L1_J40_dphi
- ▶ L1_J40_DPFI-J20XE50

- ▶ Keywords: XE, xe, J40, DPFI, J20, EM, ...

- ▶ Efficiency for L1_XE70 trigger 100% around 150 GeV in offline MET
- ▶ Efficiency for HLT_xe100 trigger 100% around 200GeV in offline MET
- ▶ In recent AtlasProduction release (20.X.X) every event passed L1 trigger also pass HLT.
- ▶ Trigger L1_J40_DPFI-J20s2XE50 correlated to MET, see lost events at plateau (not 100%)

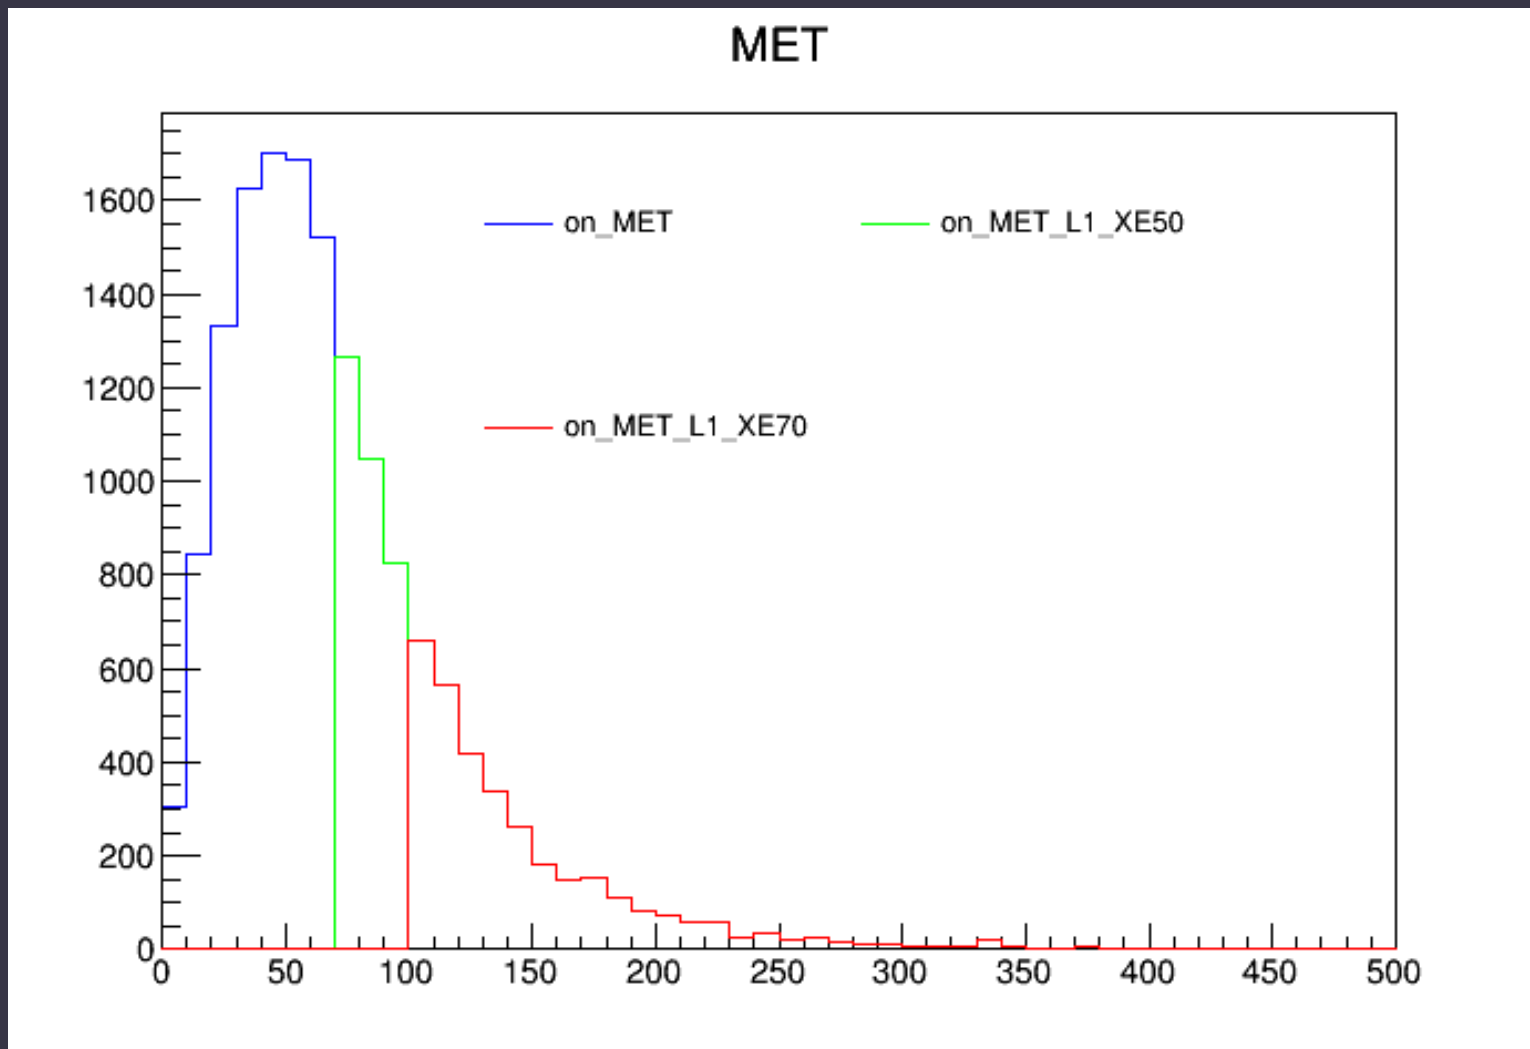

Trigger Efficiency Definition

- ▶ Measured with respect to offline reconstruction. Why?
- ▶ $N = \sigma \times \epsilon_{\text{trig}} \times \epsilon_{\text{reco}} \times L$
- ▶ So L1 eff = $N(\text{pass L1}) / N(\text{reco})$
- ▶ HLT eff = $N(\text{pass HLT}) / N(\text{reco})$
- ▶ There is alternative definition

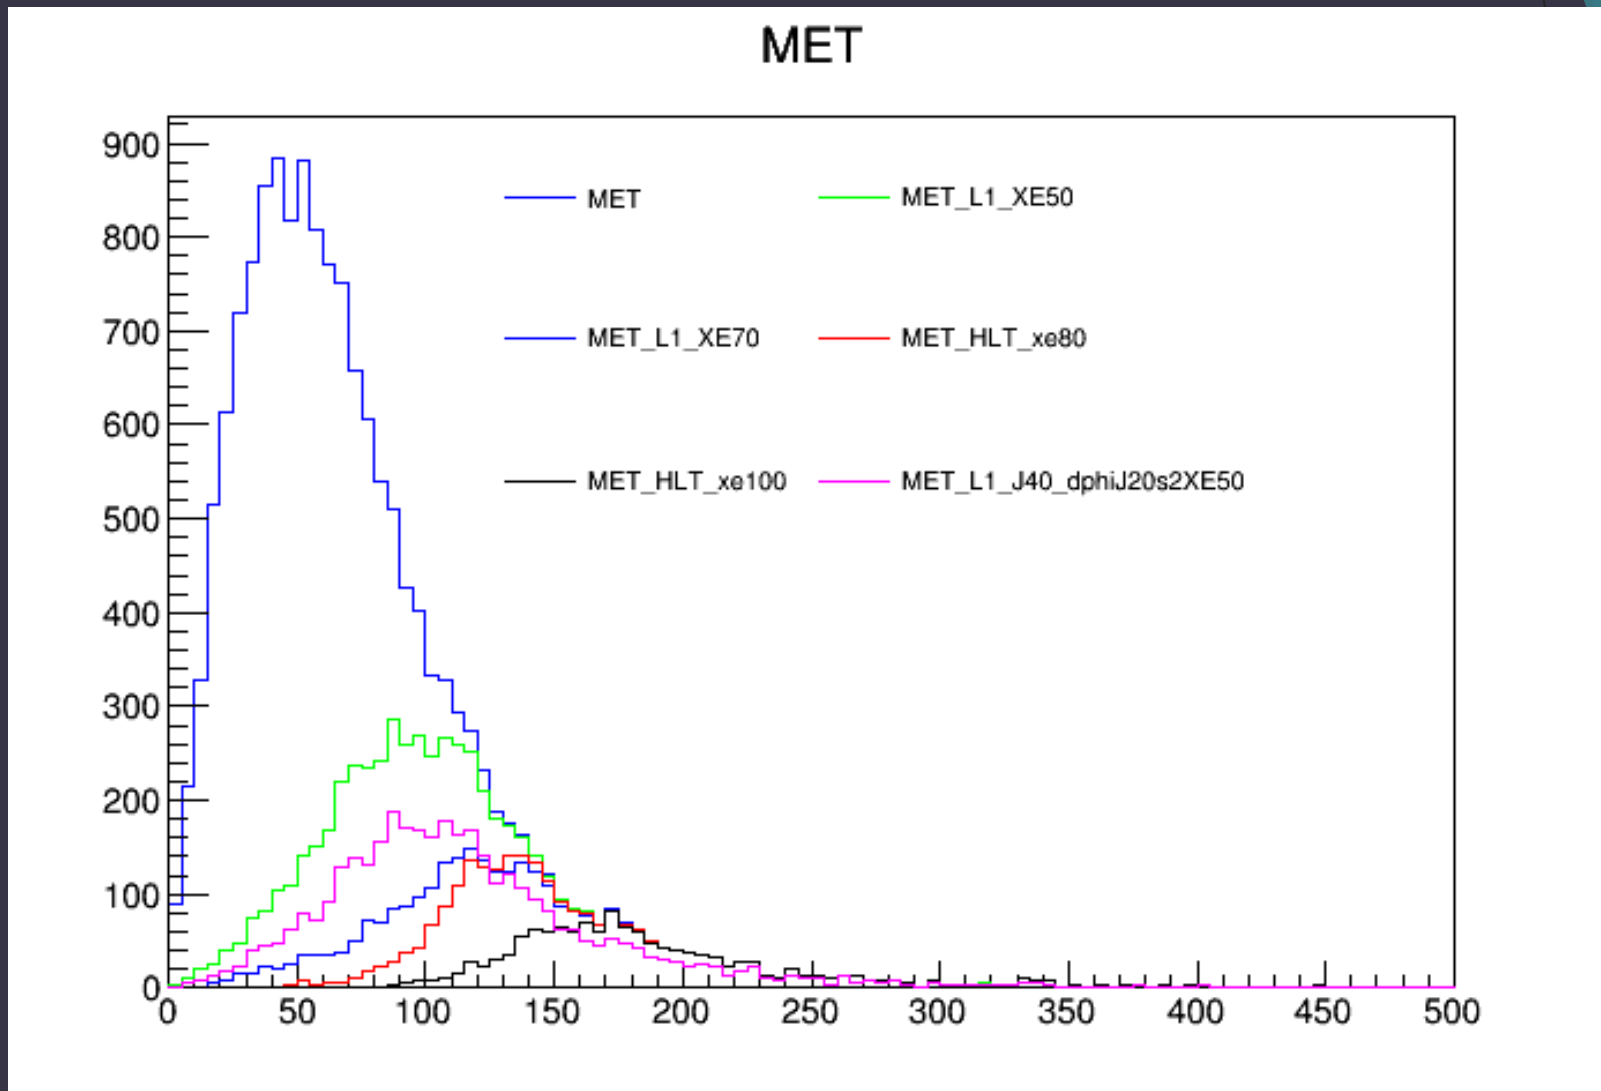

What does this means?

- ▶ Certain analysis concerned about efficiency of trigger to select events
 - ▶ cut at eff ~100% to get optimal event selection
- ▶ All analysis deal with trigger inefficiency
 - ▶ MET of certain analysis region high enough such that eff already ~100%
 - ▶ MonoHiggs, etc

TTBar (Online MET trigger)

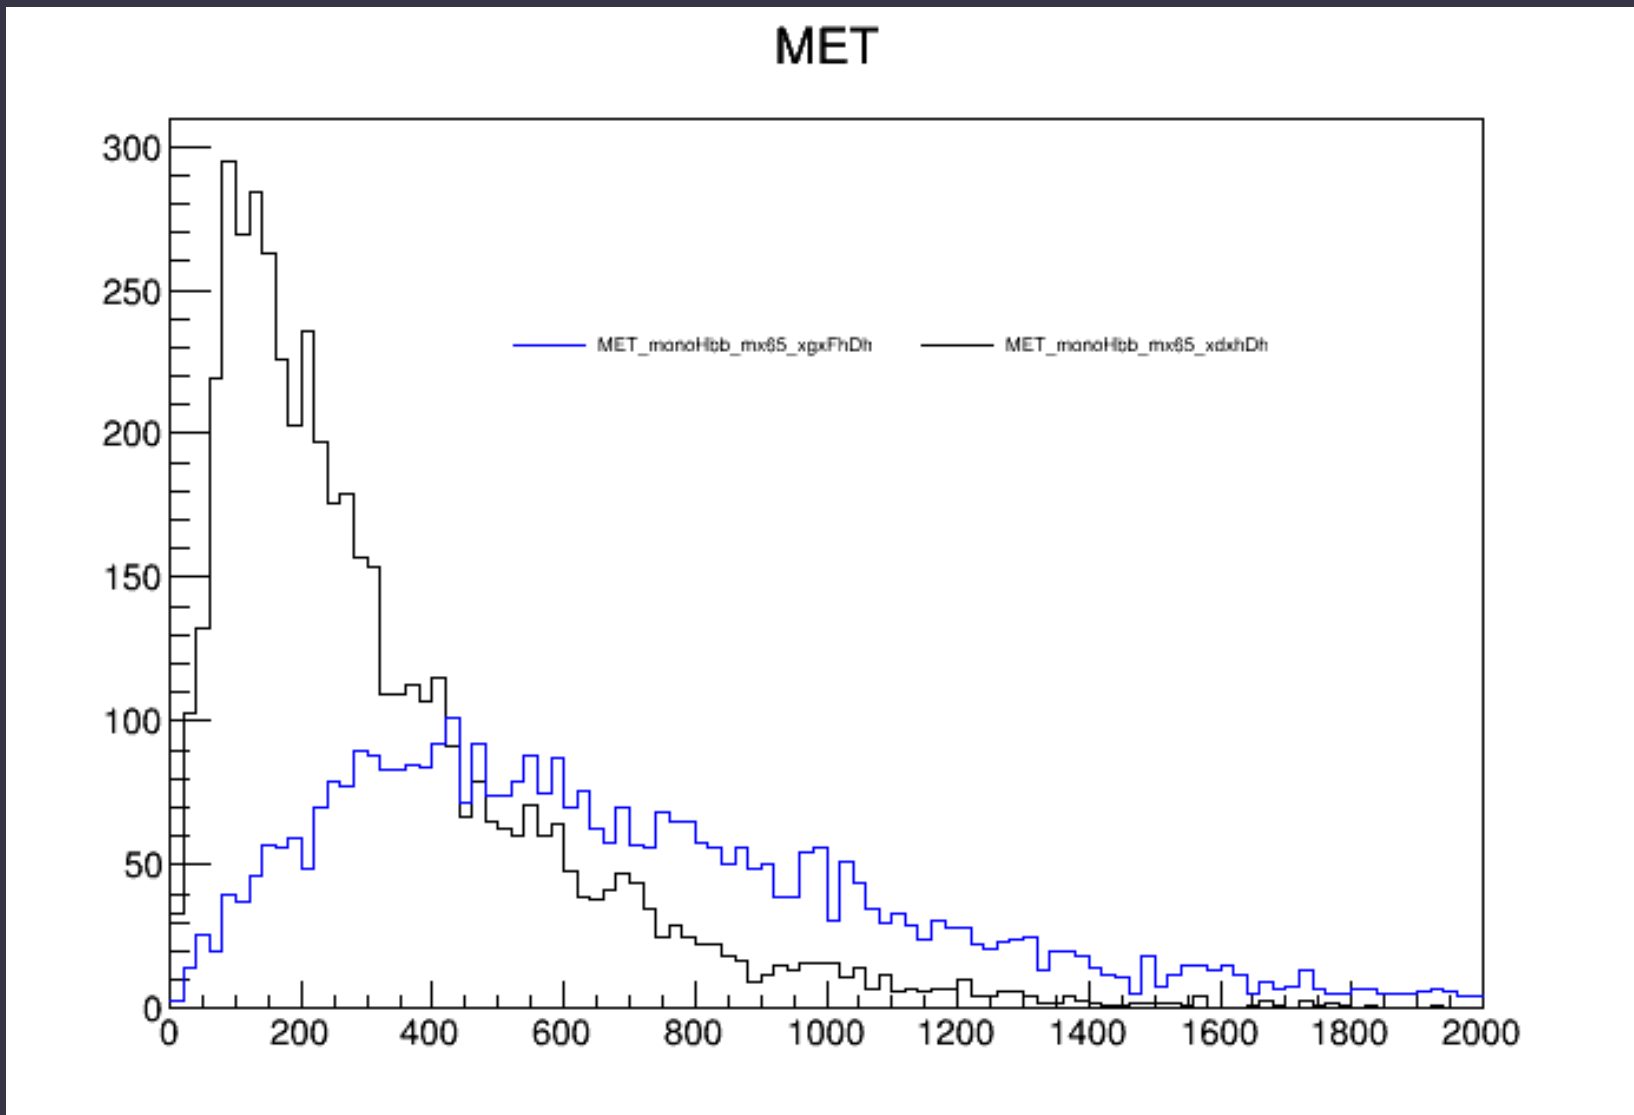

TTBar (offline MET trigger)

Ttbar (Efficiency Plots)

MonoHiggs sample ($pp > hxx > bbxx$)

Conclusion

- ▶ Trigger implementation in xAOD and Run2 is different than in Run1
- ▶ xAOD Trigger Tools has mostly been implemented, validation study is underway
- ▶ Study of trigger efficiency plots could help analysis in getting the optimum event selection
