Computer Modeling of Electron-Positron Pair Production by Channeling Radiation in Amorphous Converter

Monday 7 September 2015 16:30 (2 hours)

The radiation from the high energy (up to 10 GeV) electron beam is known to be reasonably effective positron source. An approach being possess high efficiency is to use electron beam for production of channeling radiation (CR) in a crystalline target (radiator) and subsequent electron-positron pair production in amorphous target (convertor), so called a "hybrid" solution [1].

The Mathematica [2] code BCM-1 developed by the authors enables calculating the trajectories and CR spectra of both planar and axial channeled electrons as well as positrons in crystals. The code was used to perform the comparison of the positron yield in a thin amorphous W converter produced by bremsstrahlung, by axial $\langle 100 \rangle$ and planar (110) channeling radiation in a W crystal [3].

Here we consider the radiator-converter approach at 200 MeV channeled electrons (the SPARC facility energies) for the case of using W crystalline radiator and Si, Ge and W amorphous converters. Computer modeling is carried out taking into account electron dechanneling at planar channeling in the radiator and positron stopping in the convertor.
