# Traditional picture of QCD matter in Heavy Ion Collisions

Initial Color Glass Condensate  $\longrightarrow$  Glasma thermalizes  
 $\longrightarrow$  fast equilibration of Gluons and Light flavor quarks  
high pressure, entropy  $\longrightarrow$  hydrodynamic expansion  
 $\longrightarrow$  flow as excellent probe of QCD matter.

Hadronization @  $T=155\text{MeV}$ : crossing of 2+1 flavor QCD.

Hadronic yields and  $v_n$  at RHIC and LHC measured.

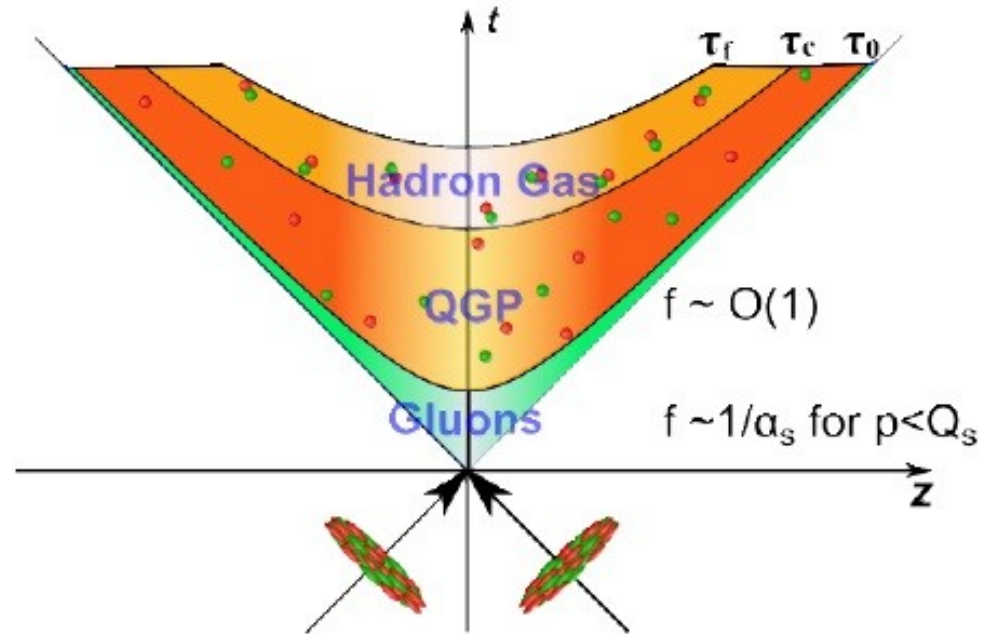

Comparison of HRG,  $T=155\text{ MeV}$ , with LHC data tests our understanding of QCD matter.

# Introduction : Fast thermalization

“how the systems evolve to thermal equilibrium in a very short time scale”

Initial: far from equilibrium

2+1 QCD Hydrodynamics  
Onset time  $\sim 1\text{fm}/c$  ?

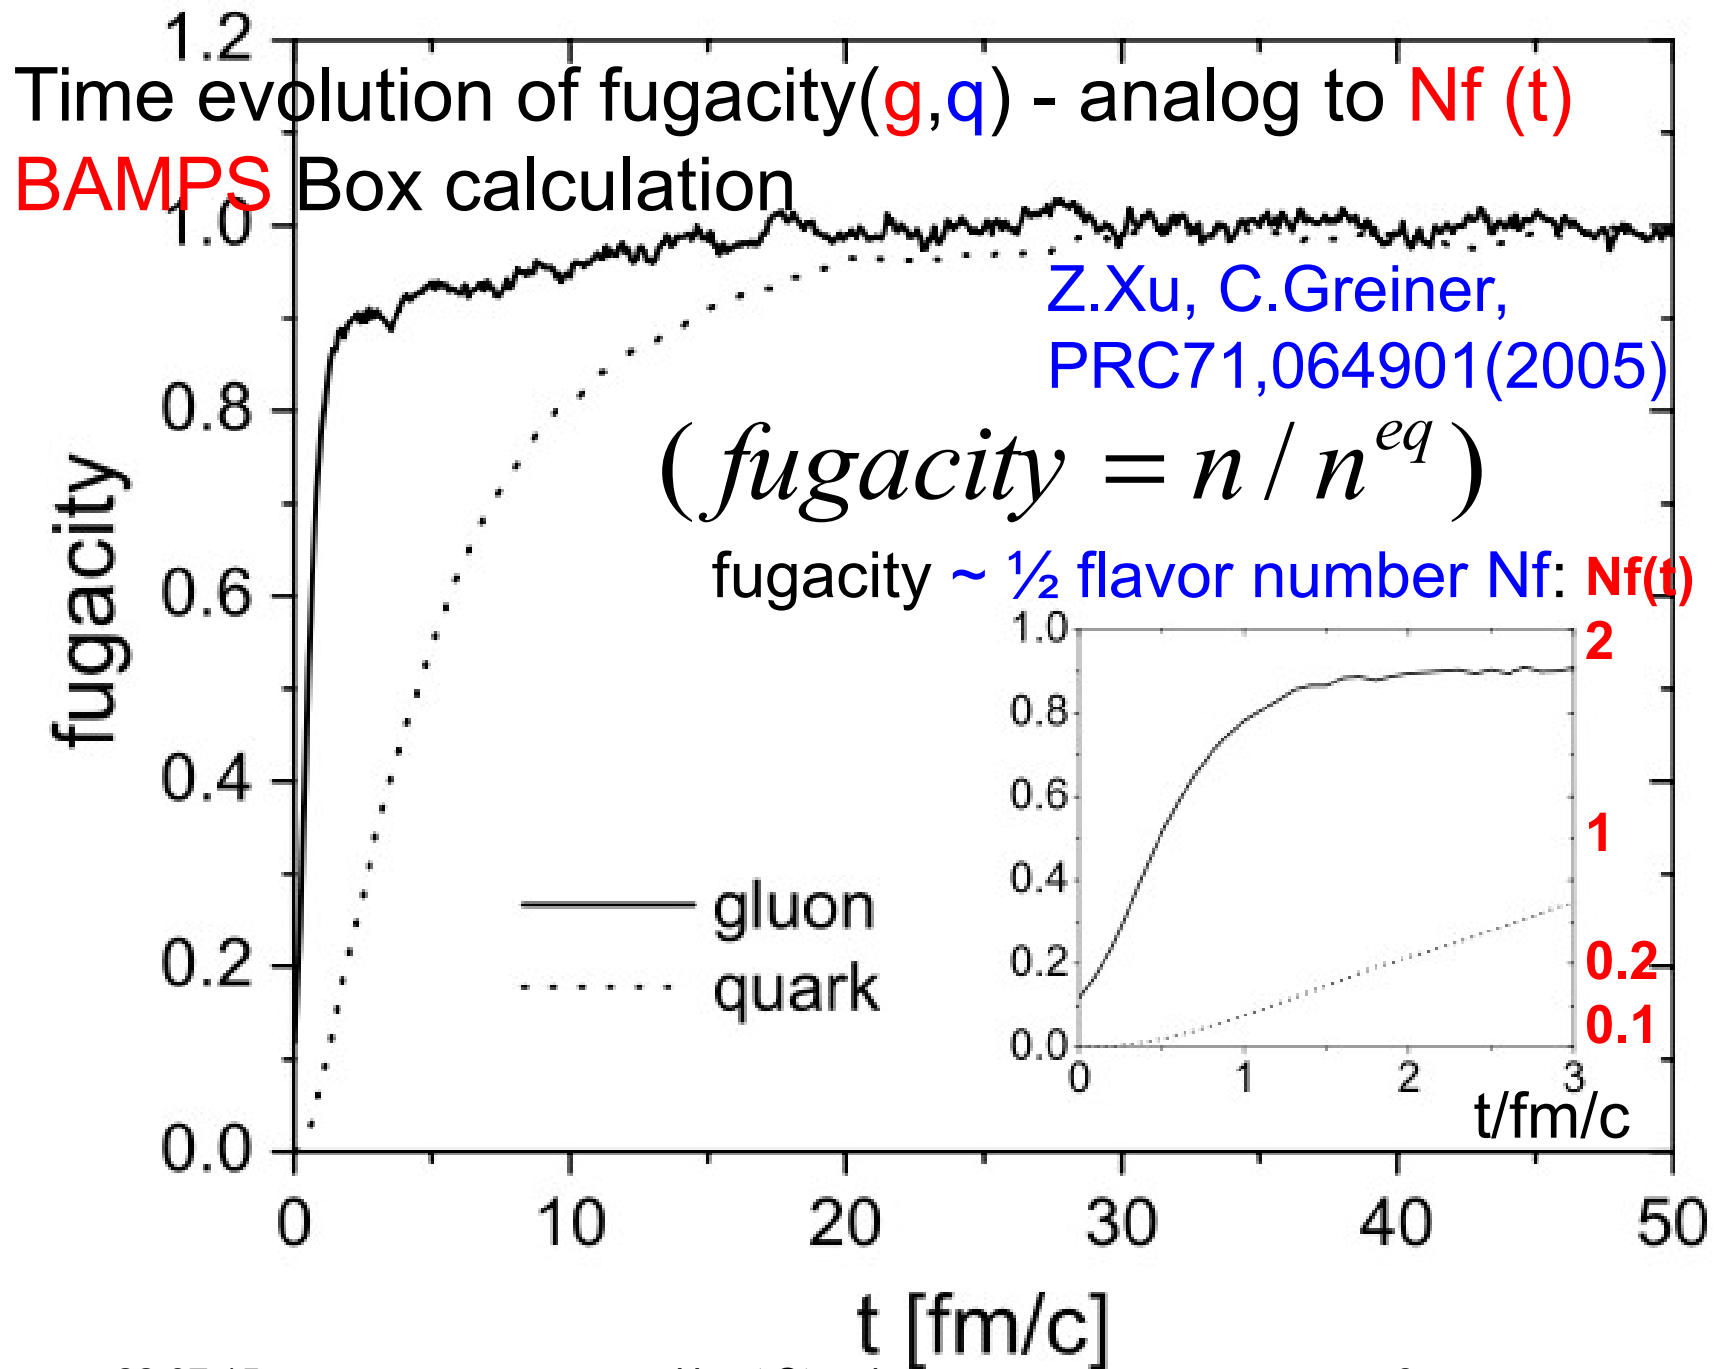

BMW: Early stage **NO QCD** ! Pure glue.

Time evolution of fugacity of gluons and quarks ( $g, q$ ) from pQCD-based rate eq.  
 T. S. Biró, B. Mueller, X. Wang, BMW, PRC48,1275 (1993)

$$(\text{fugacity} = n / n^{eq})$$

# Introducing the **Color Glass Condensate**

**CGC=effective field theory for hadrons at high energy limit**

- high energy (time dilation)  $\left\{ \begin{array}{l} \text{fluctuation(sea partons) lifetime} \\ \text{internal interaction time scales} \\ \text{small } x \left( x \sim p_z / E_{hadron} \right) \end{array} \right\} \Longrightarrow$

**gluon number increase at small x with increasing energy**

- gluon fusion  $f \sim f^2 \alpha_s \implies f \sim 1 / \alpha_s$  **Saturation**

- Saturation momentum  $Q_s(\sim \text{GeV})$**   $xG(x, Q^2) / Q^2 \rightarrow 1 / \alpha_s$

$f \sim 1 / \alpha_s (Q < Q_s)$  this feature can be inherited by initial Glasma through indirect way

# Introducing the **Glasma**

**Glasma=non-equilibrium state in between CGC and QGP**

- using CGC as initial states for nuclei

$$\longrightarrow T^{\mu\nu} = \text{diag}(\varepsilon, \varepsilon, \varepsilon, -\varepsilon)$$

**highly anisotropic** initial glasma fields

(won't last longer than  $1/Q_s$ )

- **Instabilities** --> wide range of unstable modes (up to  $Q_s$ )  
grow exponentially until saturation density

$\longrightarrow$  { redistribute momentum ---> **isotropization**  
free up quanta from classical field

$$f_0 = 1/\alpha_s(p < Q_s)$$

**initial condition amenable  
for kinetic theory**

Jean-Paul Blaizot, Bin Wu, Li Yan, Nucl.Phys. A930,139(2014)

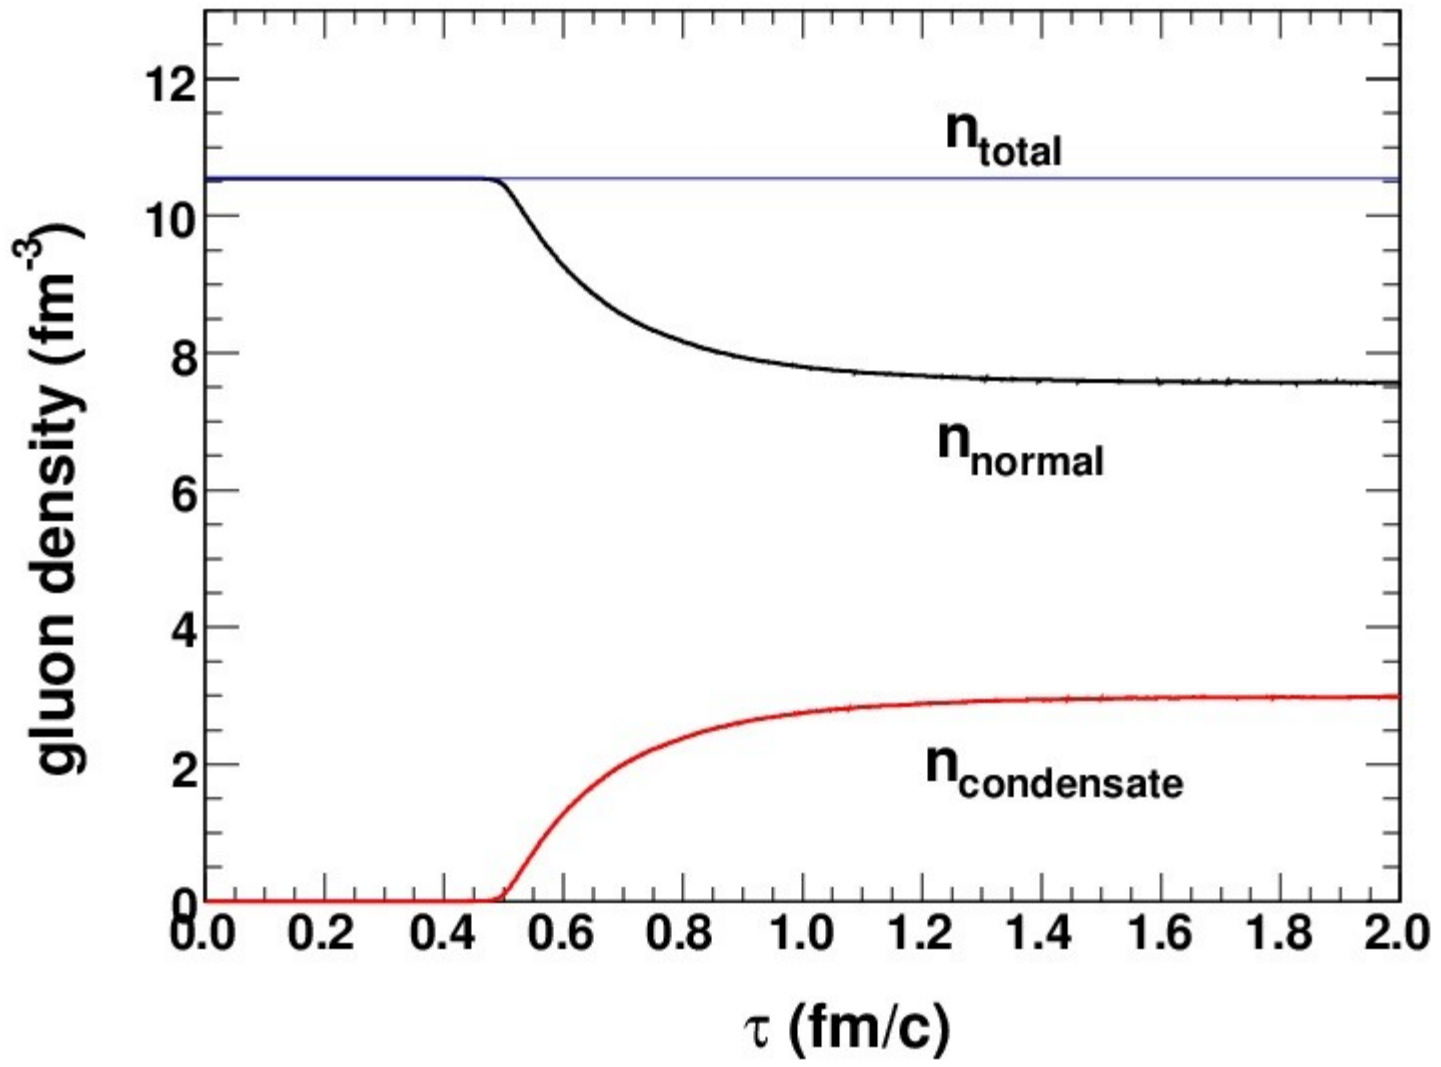

# Introducing: Overpopulation

**Overpopulation = the system contain more gluons than can be accommodated by a Bose-Einstein distribution**

initially:  $f_{init}(p) = f_0 \theta(1 - p/Q_s)$     expected final:  $f_{eq}(p) = 1/(e^{(p-\mu_{eq})/T_{eq}} - 1)$

$$\left. \begin{aligned} \varepsilon_{eq}(T_{eq}, \mu_{eq}) &= \varepsilon_0 = \int \frac{d^3 p}{(2\pi)^3} \frac{p}{e^{(p-\mu_{eq})/T_{eq}} - 1} \\ n_{eq}(T_{eq}, \mu_{eq}) &= n_0 = \int \frac{d^3 p}{(2\pi)^3} \frac{1}{e^{(p-\mu_{eq})/T_{eq}} - 1} \end{aligned} \right\} \begin{aligned} f_{critical} &= f_0 = 0.154 \\ \text{even for } \alpha_s &\sim 0.3, \\ \text{still highly } &\text{overpopulated} \end{aligned}$$

 $P_\tau = -1$  dropped

# Adding quarks in AdS/CFT: holographic QCD Terashima et al

- Adding  $N_f$  flavors → adding another kind of D-branes as probe. Karch-Katz  
Myers et.al.
- Here, we add  $N_f$  pairs of **D8-brane and anti-D8-brane**. Sakai-Sugimoto  
This model has spontaneously broken chiral symmetry, so there is **massless pion**.

Let us consider **gravity dual**, i.e. the **D8-branes in the Witten's background**.

(D8-brane and anti-D8-brane are connected and become smooth curved D8-branes as a result of the curved background.)

The D8-brane action is

$$S_{D8} = -(2\pi\alpha')^2 \mathcal{T}_{D8} \text{Tr} \int d^9x e^{-\Phi} \sqrt{-\det \tilde{g}} \frac{1}{4} \tilde{g}^{PR} \tilde{g}^{QS} F_{PQ} F_{RS} + S_{\text{Chern-Simons}}$$

where  $F$  is the field strength of the 9-dim. gauge fields on the  $N_f$  D8-branes

# Generic feature of **holographic glueball decay**

Terashima et al

- Glueballs are obviously flavor-blind. Thus couplings to mesons are universal against flavors.
- From the D8-brane action,

$$S_{\text{D8}} = -(2\pi\alpha')^2 \mathcal{T}_{\text{D8}} \text{Tr} \int d^9x e^{-\Phi} \sqrt{-\det \tilde{g}} \frac{1}{4} \tilde{g}^{PR} \tilde{g}^{QS} F_{PQ} F_{RS} + S_{\text{Chern-Simons}}$$

we see that

- (1) No glueball interaction involving more than two pions. because

$\pi$  appears in  $A_z$  but there are no  $(A_z)^n$  terms with  $n > 2$   
Decay of any glueball to  $4\pi_0$  is suppressed. Prediction of the  
holographic QCD!

- (2) Direct couplings of a glueball with more than five meson are suppressed. (implies “vector meson dominance”): No  $A^5$  term

These are from “Holographic gauge” choice

# But no mixing between **lightest glueball** and meson

Terashima et al

- Scalar mesons = transverse scalar of D8-branes, denoted by  $y$ , which is essentially  $\tau$ .
- Terms linear in  $y$  in the D8-action is:

$$\begin{aligned} g_{\nu y}|_{y=0} \partial_\mu y(z, x^\mu), & \quad g_{\nu y}|_{y=0} \partial_z y(z, x^\mu), \\ y[\partial_y g_{\tau\tau, rr, \mu r, \mu\nu}]_{y=0}, & \quad y[\partial_y \phi]_{y=0}, \\ g_{zy}|_{y=0} \partial_\mu y(z, x^\mu), & \quad g_{zy}|_{y=0} \partial_z y(z, x^\mu), \end{aligned}$$

All of these vanish for the lightest glueball.

No mixing with mesons at order  $1/\sqrt{N_c}$

This is very important to distinguish the glueball and meson.

# Decay of lightest scalar glueball

Terashima et al

Lightest glueball mass is  $M = \sqrt{7.31/9}M_{KK}$

$\rho$  meson mass is  $m_\rho = \sqrt{\lambda_1}M_{KK} = \sqrt{0.669}M_{KK}$

We have  $m_\rho < M < 2m_\rho$ . Thus no 2  $\rho$ -meson decay in holographic QCD

(In the experiment,  $M=1507\text{MeV}$ ,  $m_\rho=775\text{MeV}$ )

We will use

$$\lambda N_c / 108\pi^3 = 7.45 \times 10^{-3}$$

$$N_c = 3$$

# Possible decay process (from kinematics)

(a)  $G \rightarrow \pi\pi$  (figure 1)

(b)  $G \rightarrow \rho\pi\pi$ ,  $G \rightarrow \rho\rho \rightarrow \rho\pi\pi$  (figure 2)

(c)  $G \rightarrow \rho\pi\pi \rightarrow \pi\pi\pi\pi$ ,  $G \rightarrow \rho\rho \rightarrow \pi\pi\pi\pi$  (figure 3)

(d)  $G \rightarrow \eta'\eta'$  (figure 1)

Branching ratio for  $f_0(1500)$ :

(a) 35%

(b)+(c) 49%

(d) 7 %

**Figure 1:** A glueball  $G$  decaying to two pions  $\pi$ .

**Figure 2:** A glueball  $G$  decaying to two pions  $\pi$  and a single  $\rho$ . There are two graphs, the decay with a single vertex (Left) and the decay with two vertices (Right).

**Figure 3:** A glueball  $G$  decaying to four pions  $\pi$ . There are two graphs, the decay with two vertices (Left) and the decay with three vertices (Right).

From the effective action we have, we can compute the decay width.

For  $G \rightarrow \pi\pi$   $\frac{\Gamma_{G \rightarrow \pi\pi}}{M} = 0.040.$

Experimentally,  $\frac{\Gamma_{G \rightarrow \pi\pi}^{(\text{ex})}}{M} = \frac{109}{1507} \times 34.9\% = 0.0252.$

Good agreement.

$$G \rightarrow \rho\pi\pi \quad \text{and} \quad G \rightarrow 4\pi$$

$$\frac{\Gamma_{G \rightarrow \rho\pi\pi}}{M} \sim 1.3 \times 10^{-6} \quad \frac{\Gamma_{G \rightarrow 4\pi}}{M} \sim 2.2 \times 10^{-5}$$

This is too small, but if we set  $M/m_\rho$  to the experimental value by hand, we have

$$\frac{\Gamma_{G \rightarrow \rho\pi\pi}}{M} = 0.096 \quad \frac{\Gamma_{G \rightarrow 4\pi}}{M} \sim 0.0087$$

Thus 
$$\frac{\Gamma_{G \rightarrow 4\pi} + \Gamma_{G \rightarrow \rho\pi\pi}}{M} \sim 0.105$$

Experimentally, 
$$\frac{\Gamma_{G \rightarrow 4\pi}^{(\text{ex})}}{M} = \frac{109}{1507} \times 49.5\% = 0.0358$$

**Consistent**

(In particular, taking into account the masslessness of the pions)

**Terashima et al: First attempt** in computing decays of glueballs to mesons using a holographic QCD (Sakai-Sugimoto model).

The holographic QCD is, in principle, equivalent to QCD.

We therefore expect that the holographic approach should provide interesting information on strong coupling physics of QCD.

Explicit couplings between the lightest glueball and the mesons are given, and the associated decay products/widths are calculated.

Our results are consistent with the experimental data of the decay for the  $f_0(1500)$  which is thought to be the best candidate of a glueball in the hadronic spectrum.

We have shown that there is no mixing with the mesons at the leading order.

Decay of any glueball to  $4\pi_0$  is suppressed.

**This is a prediction of the holographic QCD!**
