## Blast-wave model description of the Hanbury-Brown -Twiss radii in pp collisions at LHC energies

*Wednesday, 4 November 2015 09:25 (25 minutes)*

The blast wave model is applied to the recent data on HBT radii in pp collisions, measured by the ALICE collaboration. A reasonable description of data is obtained for a rather low temperature of the kinetic freeze-out,  $T = 100$  MeV, and the transverse profile corresponding to the emission from a shell of a fairly small width of about 1.5 fm. The size and the life-time of the produced system are determined for various multiplicities of the produced particles.
