Two-particle correlations in pp collisions at 13 TeV measured with CMS

Wednesday 4 November 2015 16:05 (25 minutes)

Results on two-particle angular correlations for charged particles emitted in pp collisions at a center-of-mass energy of 13 TeV are presented. The correlations are studied as a function of charged-particle multiplicity and transverse momentum (pT). In high-multiplicity events, a long-range ($|\eta| > 2.0$), near-side ($\Delta_\phi = 0$) structure emerges in the two-particle $\Delta_\eta - \Delta_\phi$ correlation functions. The overall correlation strength is similar to that found in earlier pp data at 7 TeV, but is measured up to much higher multiplicity values.
