

Detectors for Particle Physics

Calorimetry

D. Bortoletto
University of Oxford

What is a calorimeter ?

- In nuclear and particle physics calorimetry refers to the detection of particles through total absorption in a block of matter
 - The measurement process is destructive for almost all particle
 - The exception are muons (and neutrinos) → identify muons easily since they penetrate a substantial amount of matter
- In the absorption, almost all particle's energy is eventually converted to heat → calorimeter
- Calorimeters are essential to measure neutral particles

Electromagnetic shower

- Dominant processes at high energies ($E > \text{few MeV}$):

- Photons: Pair production

$$\sigma_{pair} \approx \frac{7}{9} \left(4\alpha r_e^2 Z^2 \ln \frac{183}{Z^{1/3}} \right) = \frac{7}{9} \frac{A}{N_A X_0}$$

$$I(x) = I_0 e^{-\mu x} \quad \mu = \frac{7}{9} \frac{\rho}{X_0}$$

μ = attenuation coefficient

X_0 = radiation length in [cm] or [g/cm²]

$$X_0 = \frac{A}{4\pi N_A Z^2 r_e^2 \ln \frac{183}{Z^{1/3}}}$$

- Electrons: Bremsstrahlung

$$\frac{dE}{dx} = 4\alpha N_A \frac{Z^2}{A} r_e^2 E \ln \frac{183}{Z^{1/3}} = \frac{E}{X_0}$$

$$E = E_0 e^{-x/X_0}$$

After traversing $x=X_0$ the electron has only $1/e=37\%$ of its initial energy

Analytic shower Model

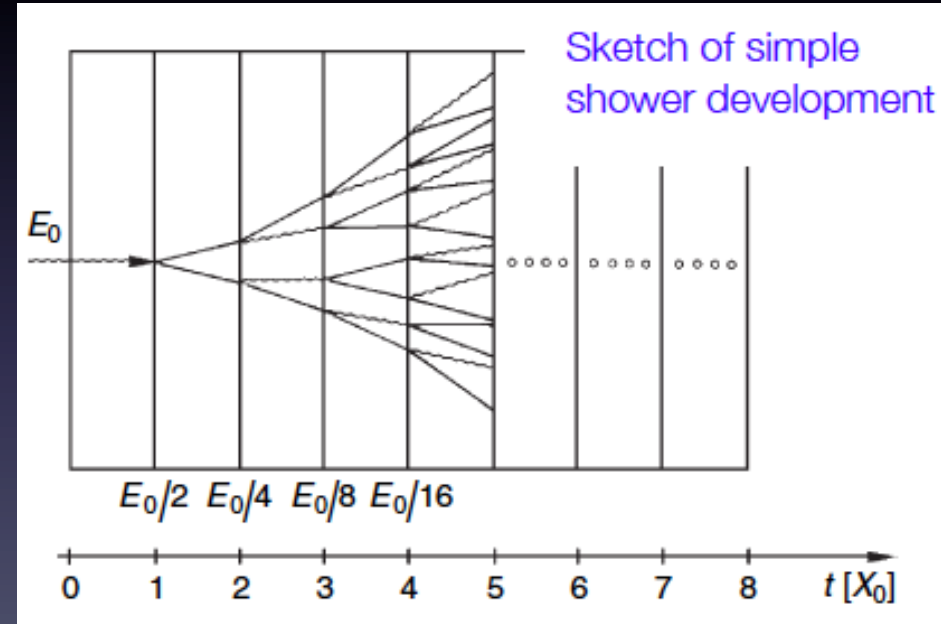

- Simplified model [Heitler]: shower development governed by X_0
 - e^- loses $[1 - 1/e] = 63\%$ of energy in 1 X_0 (Brems.)
 - the mean free path of a γ is $9/7 X_0$ (pair prod.)

- Assume:

- $E > E_c$: no energy loss by ionization/excitation

- Simple shower model:

- $N(t)=2^t$ particles after $t =x/X_0$ each with energy $E(t)=E_0/2^t$
- Stops if $E(t) < E_c = E_0 2^{-t_{\max}}$
- Location of shower maximum at

$$t_{\max} = \frac{\ln(E / E_c)}{\ln 2} \propto \ln \left(\frac{E}{E_c} \right)$$

$$N_{\max} = 2^{t_{\max}} = \frac{E_0}{E_c}$$

Longitudinal shower distribution

- Differences between electrons and photons generated showers
- Some photons penetrating (almost) the entire slab without interacting (peak at 0)

$$t_{\max} = \ln\left(\frac{E_0}{E_c}\right) + C_{ey}$$

$C_{ey} = -0.5$ for photons
 $C_{ey} = -1$ for electrons

Longitudinal shower containment

- EM calorimeter can be quite compact. Since $t_{\max} \approx \ln(E) \rightarrow$ calorimeter thickness must increase as $\ln(E)$
- After shower max e^+/e^- will stop in $\approx 1X_0$
- To absorb 95% of photons after shower max $\approx 9X_0$ of material are needed
- The energy leakage is mainly due to photons
- A useful expression to indicate 95% shower containment is:

$$L(95\%) = t_{\max} + 0.08 Z + 9.6 [X_0]$$

$$E_C \approx 10 \text{ MeV} \quad E_0 = 1 \text{ GeV} \quad \Rightarrow t_{\max} = \ln 100 / \ln 2 \approx 6.6 \quad N_{\max} = 100$$

$$E_0 = 100 \text{ GeV} \quad \Rightarrow t_{\max} = \ln 10,000 / \ln 2 \approx 9.9 \quad N_{\max} = 10,000$$

| | Scint. | LAr | Fe | Pb | W |
|------------------|--------|-----|------|------|------|
| $X_0(\text{cm})$ | 34 | 14 | 1.76 | 0.56 | 0.35 |

A 100 GeV e^- is contained in 17.5 cm Fe or 5.6 cm Pb

Lateral development of EM shower

- Opening angle:
 - bremsstrahlung and pair production

$$\langle \theta^2 \rangle \approx \left(\frac{m_e c^2}{E_e} \right)^2 = \frac{1}{\gamma^2}$$

- multiple coulomb scattering [Molière theory]

$$\langle \theta \rangle = \frac{E_s}{E_e} \sqrt{\frac{x}{X_0}} \quad \text{where} \quad E_s = \sqrt{\frac{4\pi}{\alpha}} (m_e c^2) = 21.2 \text{ MeV}$$

- Main contribution from low energy e^- as $\langle \theta \rangle \sim 1/E_e$, i.e. for e^- with $E < E_c$

Molière Radius

$$R_M = \frac{E_s}{E_c} X_0 \approx \frac{21.2 \text{ MeV}}{E_c} X_0$$

- Assuming the approximate range of electrons to be X_0 yields $\langle \theta \rangle \approx 21.2 \text{ MeV}/E_e \rightarrow$ lateral extension: $R = \langle \theta \rangle X_0$

Lateral development of EM shower

- Inner part is due to Coulomb's scattering of electron and positron
- Outer part is due to low energy γ produced in Compton's scattering, photo-electric effect etc.
 - Predominant part after shower max especially in high Z absorbers

$$\frac{dE}{dr} = \alpha e^{-r/R_M} + \beta e^{-r/\lambda_{\min}}$$

- The shower gets wider at larger depth
- An infinite cylinder of radius $2R_M$ contains 95% of the shower

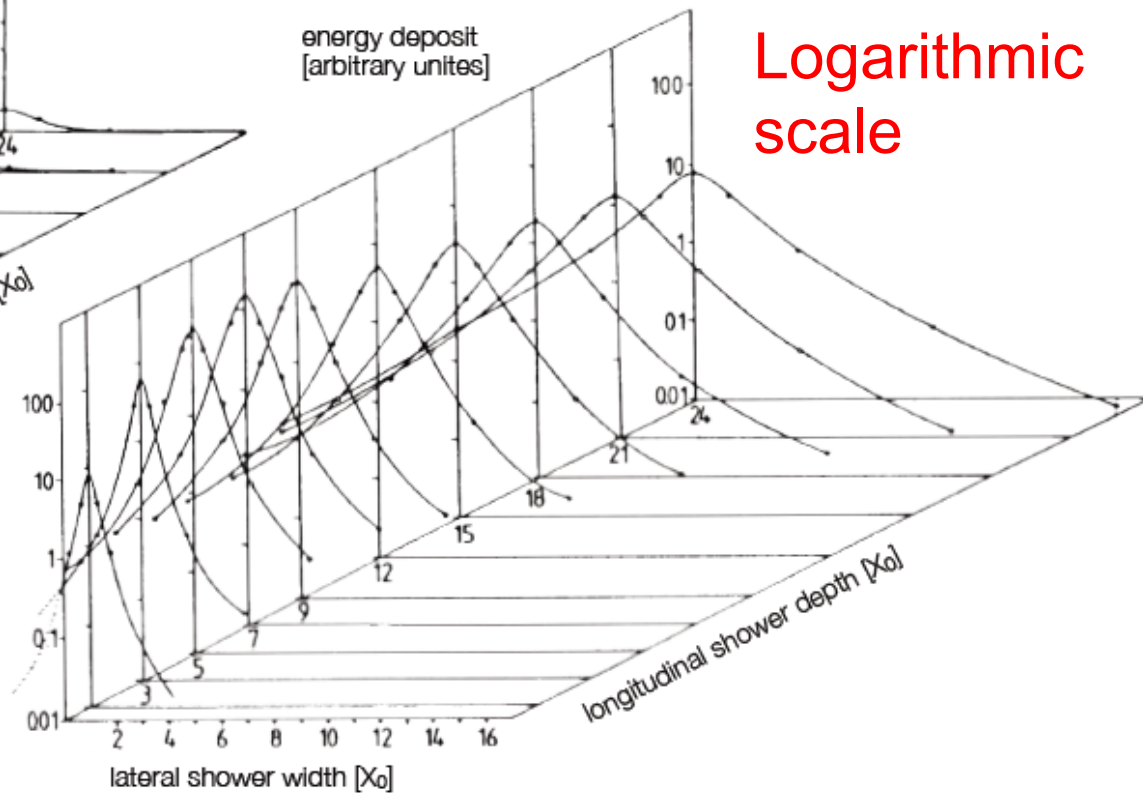

3D EM Shower development

Logarithmic scale

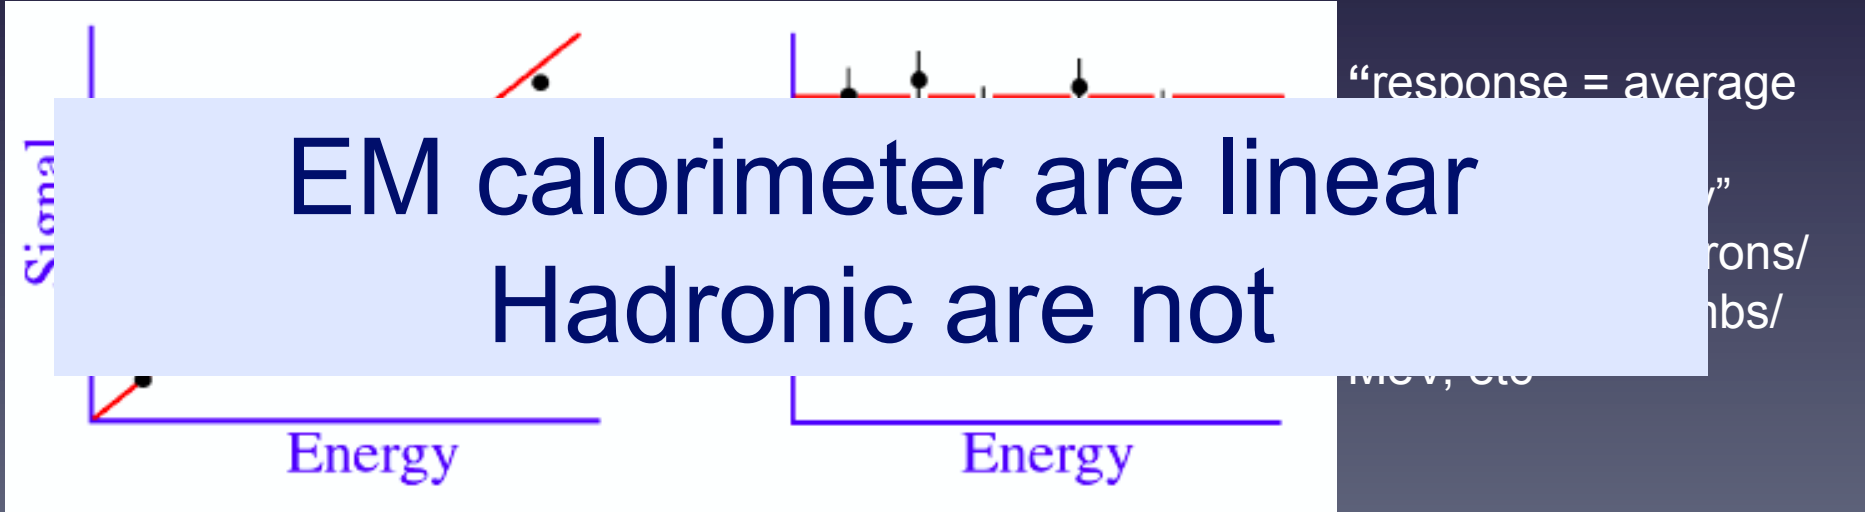

EM shower development in liquid krypton ($Z=36$, $A=84$)

GEANT simulation of a 100 GeV electron shower in the NA48 liquid Krypton calorimeter (D.Schinzel)

Energy Measurement

- How we determine the energy of a particle from the shower?
 - Detector response → Linearity
 - The average calorimeter signal vs. the energy of the particle
 - Homogenous and sampling calorimeters
 - Compensation (for hadronic showers)
 - Detector resolution → Fluctuations
 - Event to event variations of the signal
 - What limits the accuracy at different energies?

EM calorimeter are linear
Hadronic are not

Sources of Non Linearity

Signal linearity for electromagnetic showers

- Instrumental effects
 - Saturation of gas detectors, scintillators, photo-detectors, Electronics
- Response varies with something that varies with energy
- Examples:
 - Deposited energy “counts” differently, depending on depth
 - And depth increases with energy
- Leakage (increases with energy)

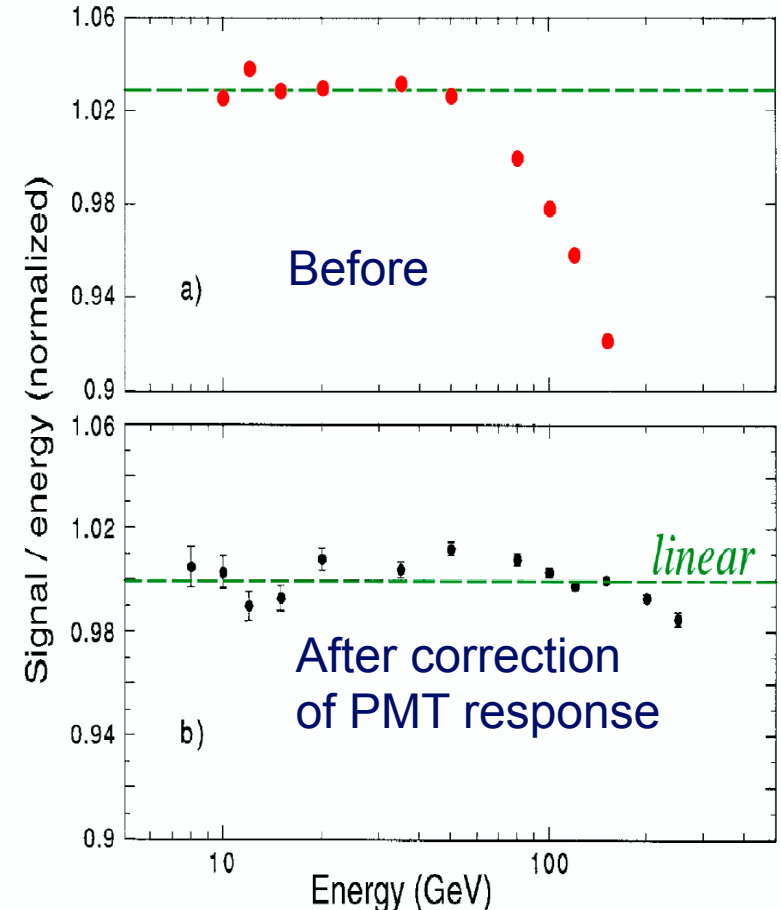

FIG. 3.1. The em calorimeter response as a function of energy, measured with the QFCAL calorimeter, before (a) and after (b) precautions were taken against PMT saturation effects. Data from [Akc 97].

EM Calorimeter configurations

■ Total absorption

- Electrons and photons stop in calorimeter
- Scintillation proportional to energy of electron
- Usually non-organic scintillator (BGO, PbWO_4, \dots) or liquid Xe
- Advantage: Excellent energy resolution
 - see all charged particles in the shower (but for shower leakage) → best statistical precision
 - Uniform response → good linearity
- Disadvantages:
 - cost and limited segmentation

If W is the mean energy required to produce a signal (eg an e^- -ion pair in a noble liquid or a 'visible' photon in a crystal)

$$\frac{\sigma_E}{E} = \frac{1}{\sqrt{n}} = \frac{1}{\sqrt{E/W}}$$

■ Examples:

- B factories: small photon energies
- CMS ECAL which was optimized for $H \rightarrow \gamma\gamma$

Homogenous calorimeters

Barrel: 62K $2.2 \times 2.2 \times 23$ cm³ crystals

Endcap: 15K $3 \times 3 \times 22$ cm³ crystals

Development of PbWO_4 radiation hard crystals

1% resolution at 30 GeV

EM Calorimeter configurations

■ Sampling Calorimeter

- One material to induce showering (high Z)
- Another to detect particles (typically by counting number of charged tracks)
- Many layers sandwiched together
- Resolution $\propto E^{-1/2}$

■ Advantages

- Depth segmentation
- Spatial segmentation

■ Disadvantages:

- Only part of shower seen, less precise

■ Examples

- ATLAS ECAL
- Most HCALs

■ Sampling fraction

$$f_{\text{sampling}} = \frac{E_{\text{visible}}}{E_{\text{deposited}}}$$

Scintillators as active layer;
signal readout via photo multipliers

Scintillators as active layer; wave length shifter to convert light

Charge amplifier

Active medium: LAr; absorber embedded in liquid serve as electrodes

Ionization chambers between absorber plates

• Ac

HV
 r gap
 r
 eel.

Energy resolution

■ Ideally, if all shower particles counted:

$$E \propto N \quad \sigma_E \approx \sqrt{N} \approx \sqrt{E}$$

■ In practice

$$\sigma_E = a\sqrt{E} \oplus bE \oplus c$$

$$\frac{\sigma_E}{E} = \frac{a}{\sqrt{E}} \oplus b \oplus \frac{c}{E}$$

■ a: stochastic term

- intrinsic statistical shower fluctuations
- sampling fluctuations
- signal quantum fluctuations (e.g. photo-electron statistics)

■ b: constant term

- inhomogeneities (hardware or calibration)
- imperfections in calorimeter construction (dimensional variations, etc.)
- non-linearity of readout electronics
- fluctuations in longitudinal energy containment (leakage can also be $\sim E^{-1/4}$)
- fluctuations in energy lost in dead material before or within the calorimeter

■ c: noise term

- readout electronic noise
- Radio-activity, pile-up fluctuations

Effects on energy resolution

ATLAS EM calorimeter

$$\frac{\sigma(E)}{E} = \frac{10\%}{\sqrt{E}} \oplus \frac{170\text{MeV}}{E} \oplus 0.7\%$$

- Different effects have different energy dependence

- Sampling fluctuations

$$\sigma/E \sim E^{-1/2}$$

- shower leakage

$$\sigma/E \sim E^{-1/4}$$

- electronic noise $\sigma/E \sim E^{-1}$

- structural non-uniformities:

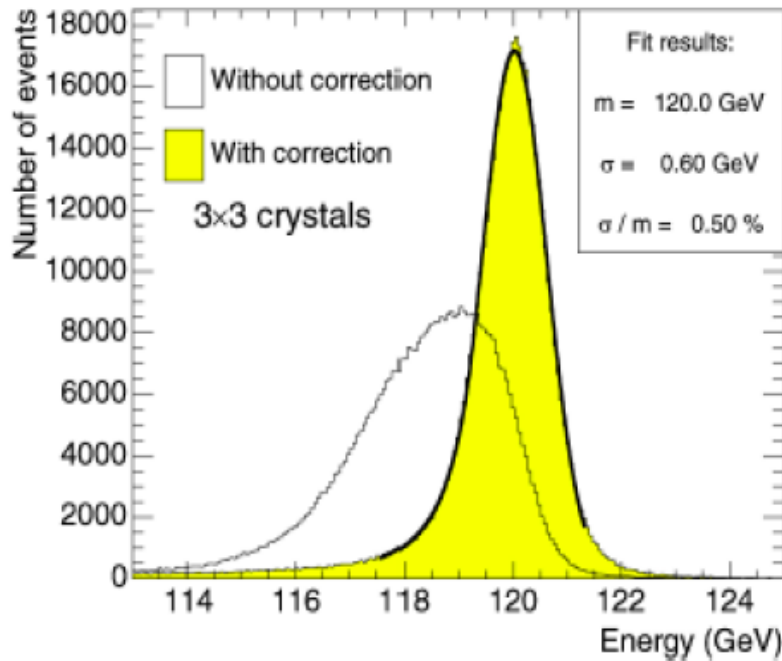

$$\sigma/E = \text{constant}$$

- $\sigma_{\text{tot}}^2 = \sigma_1^2 + \sigma_2^2 + \sigma_3^2 + \sigma_4^2$

+ ...

CMS ECAL resolution

Correction for radial loss

The sampling term is 3 times smaller than ATLAS; other terms are similar

$$\frac{\sigma(E)}{E} = \frac{2.8\%}{\sqrt{E}} \oplus \frac{120 \text{ MeV}}{E} \oplus 0.3\%$$

Stoch. Noise Const.

Homogeneous vs Sampling

E in GeV

| Technology (Experiment) | Depth | Energy resolution | Date |
|--|------------|---|------|
| NaI(Tl) (Crystal Ball) | $20X_0$ | $2.7\%/E^{1/4}$ | 1983 |
| Bi ₄ Ge ₃ O ₁₂ (BGO) (L3) | $22X_0$ | $2\%/ \sqrt{E} \oplus 0.7\%$ | 1993 |
| CsI (KTeV) | $27X_0$ | $2\%/ \sqrt{E} \oplus 0.45\%$ | 1996 |
| CsI(Tl) (BaBar) | $16-18X_0$ | $2.3\%/E^{1/4} \oplus 1.4\%$ | 1999 |
| CsI(Tl) (BELLE) | $16X_0$ | 1.7% for $E_\gamma > 3.5$ GeV | 1998 |
| PbWO ₄ (PWO) (CMS) | $25X_0$ | $3\%/ \sqrt{E} \oplus 0.5\% \oplus 0.2/E$ | 1997 |
| Lead glass (OPAL) | $20.5X_0$ | $5\%/ \sqrt{E}$ | 1990 |
| Liquid Kr (NA48) | $27X_0$ | $3.2\%/ \sqrt{E} \oplus 0.42\% \oplus 0.09/E$ | 1998 |
| Scintillator/depleted U (ZEUS) | $20-30X_0$ | $18\%/ \sqrt{E}$ | 1988 |
| Scintillator/Pb (CDF) | $18X_0$ | $13.5\%/ \sqrt{E}$ | 1988 |
| Scintillator fiber/Pb spaghetti (KLOE) | $15X_0$ | $5.7\%/ \sqrt{E} \oplus 0.6\%$ | 1995 |
| Liquid Ar/Pb (NA31) | $27X_0$ | $7.5\%/ \sqrt{E} \oplus 0.5\% \oplus 0.1/E$ | 1988 |
| Liquid Ar/Pb (SLD) | $21X_0$ | $8\%/ \sqrt{E}$ | 1993 |
| Liquid Ar/Pb (H1) | $20-30X_0$ | $12\%/ \sqrt{E} \oplus 1\%$ | 1998 |
| Liquid Ar/depl. U (DØ) | $20.5X_0$ | $16\%/ \sqrt{E} \oplus 0.3\% \oplus 0.3/E$ | 1993 |
| Liquid Ar/Pb accordion (ATLAS) | $25X_0$ | $10\%/ \sqrt{E} \oplus 0.4\% \oplus 0.3/E$ | 1996 |

Homogeneous

Sampling

Hadron Showers

- Hadrons interact with detector material also through the strong interaction
- Hadron calorimeter measurement:

Elementary to track measurement
 way to measure their energy
 secondary particles are produced
 reactions → hadronic cascades
 particles (π, η) initiate EM shower
 as nuclear binding energy or target recoil

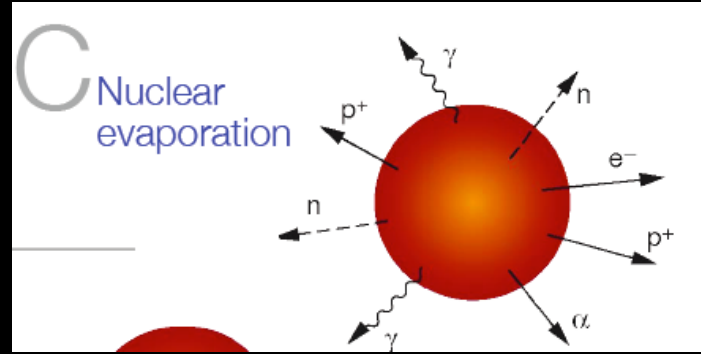

Hadronic shower

Hadronic interaction:

Elastic:

Inelastic:

Hadronic shower

Hadronic interaction Cross section

$$\sigma_{Tot} = \sigma_{el} + \sigma_{inel}$$

$$\sigma_{el} \approx 10mb \quad \sigma_{inel} \approx A^{2/3}$$

$$\sigma_{Tot} = \sigma_{tot}(pp)A^{2/3}$$

where: $\sigma_{tot}(pp)$ increases with \sqrt{s}

Hadronic interaction length

$$\lambda_{int} = \frac{1}{\sigma_{tot} \cdot n} = \frac{A\rho}{\sigma_{pp}A^{2/3}N_A} \approx (35g/cm^2)A^{1/3}$$

$$N(x) = N(0)e^{-x/\lambda_{int}}$$

λ_{int} characterizes both longitudinal and transverse shower profile

Rule of thumb argument: the geometric cross section goes as the square of the size of the nucleus, a_N^2 , and since the nuclear radius scales as $a_N \sim A^{1/3}$, the nuclear mean free path in gm/cm^2 units scales as $A^{1/3}$.

Hadronic vs EM showers

Hadronic vs. electromagnetic interaction length:

$$\left. \begin{aligned} X_0 &\sim \frac{A}{Z^2} \\ \lambda_{\text{int}} &\sim A^{1/3} \end{aligned} \right\} \rightarrow \frac{\lambda_{\text{int}}}{X_0} \sim A^{4/3}$$

$$\lambda_{\text{int}} \gg X_0$$

[$\lambda_{\text{int}}/X_0 > 30$ possible; see below]

Some numerical values for materials typical used in hadron calorimeters

| | λ_{int} [cm] | X_0 [cm] |
|--------|-----------------------------|------------|
| Szint. | 79.4 | 42.2 |
| LAr | 83.7 | 14.0 |
| Fe | 16.8 | 1.76 |
| Pb | 17.1 | 0.56 |
| U | 10.5 | 0.32 |
| C | 38.1 | 18.8 |

Typical
Longitudinal size: $6 \dots 9 \lambda_{\text{int}}$
[95% containment]

[EM: 15-20 X_0]

Typical
Transverse size: one λ_{int}
[95% containment]

[EM: 2 R_M ; compact]

Hadronic calorimeter need more depth
than electromagnetic calorimeter ...

Material dependence

- λ_{int} : mean free path between nuclear collisions: $\lambda_{int} \text{ (g cm}^{-2}\text{)} \propto A^{1/3}$
- λ_{abs} : Hadronic absorption length for inelastic processes
- Hadron showers are much longer than EM ones. Length depends on Z

Hadronic shower: Longitudinal development

Hadronic Shower

π^0 can deposit energy via EM processes

f_{EM} = fraction of hadron energy deposited via EM processes

- Electromagnetic
 - ionization, excitation (e^\pm)
 - photo effect, scattering (γ)
- Hadronic
 - ionization (π^\pm, ρ)
 - invisible energy (binding, recoil)
- e = response to the EM shower component
- h = response to the non-EM component

FIG. 2.22. Comparison between the experimental results on the em fraction of pion-induced showers in the (copper-based) QFCAL and (lead-based) SPACAL detectors. Data from [Ake 97] and [Aco 92b].

Energy resolution and compensation

- Compensation for loss of invisible energy: $e/h=1$
- Non compensating detectors show deviations from scaling in $1/\sqrt{E}$ and non-linearity in signal response
- How can compensation be achieved?
 - Reduce e and increase h component
 - High-Z material such as U absorbs larger fraction of energy of electromagnetic part of shower \rightarrow decreases e
 - Tuning n response. Interaction of n with hydrogen (large cross section) through elastic n - p scattering \rightarrow efficient sampling of n through the detection of recoiling proton \rightarrow increases h
 - Tune the ratio of absorber to active material which sets e/h
 - Other techniques: Software compensation

FIG. 3.14. The response to pions as a function of energy for three calorimeters with different e/h values: the WA1 calorimeter ($e/h > 1$, [Abr 81]), the HELIOS calorimeter ($e/h \approx 1$, [Ake 87]) and the WA78 calorimeter ($e/h < 1$, [Dev 86, Cat 87]). All data are normalized to the results for 10 GeV.

Pb/Scintillator

Energy resolution of hadronic showers

- Fluctuations in visible energy (ultimate limit of hadronic energy resolution)
 - fluctuations of nuclear binding energy loss in high-Z materials $\sim 15\%$
- Fluctuations in the EM shower fraction, f_{em}
 - Dominating effect in most hadron calorimeters ($e/h > 1$)
 - Fluctuations are asymmetric in pion showers
 - Differences between p , π induced showers (No leading π^0 in proton showers)
- Sampling fluctuations only minor contribution to hadronic resolution in non-compensating calorimeter

Energy resolution of hadron showers

- Hadronic energy resolution of non-compensating calorimeters does not scale with $1/\sqrt{E}$ but as

$$\frac{\sigma_E}{E} = \frac{a}{\sqrt{E}} \oplus b \left(\frac{E}{E_0} \right)$$

- But in practice we use

$$\frac{\sigma_E}{E} = \frac{a}{\sqrt{E}} \oplus b$$

A realistic calorimetric system

Typical Calorimeter: two components ...

Electromagnetic (EM) +
Hadronic section (Had) ...

Different setups chosen for
optimal energy resolution ...

But:

Hadronic energy measured in
both parts of calorimeter ...

Needs careful consideration of
different response ...

sci. fibres, read out by phototubes

Hadronic calorimeters resolution

CMS

- HCAL only

$$\sigma/E = (93.8) \%/ \sqrt{E} \oplus (7.4) \%$$

- ECAL+HCAL

$$\sigma/E = (82.6) \%/ \sqrt{E} \oplus (4.5) \%$$

ATLAS

- Standalone tile calorimeter

$$\sigma/E = (52.9) \%/ \sqrt{E} \oplus (5.7) \%$$

- Improved resolution using full calorimetric system (ECAL+HCAL)

$$\sigma/E = (42) \%/ \sqrt{E} \oplus (2) \%$$

Future calorimeters

- Concentrate on improvement of jet energy resolution to match the requirement of the new physics expected in the next 30-50 years:
- Two approaches:
 - minimize the influence of the calorimeter and measure jets using the combination of all detectors → Particle Flow
 - measure the shower hadronic shower components in each event & weight directly access the source of fluctuations → Dual (Triple) Readout
- Also looking for more radiation hard crystals

Crystals for HL-LHC

- LSO/LYSO is a heavy (7.4 g/cm³) crystal with bright (200 times light of PWO) and fast (40 ns) scintillation light. It has been widely used in the medical industry.
- Very rad-had

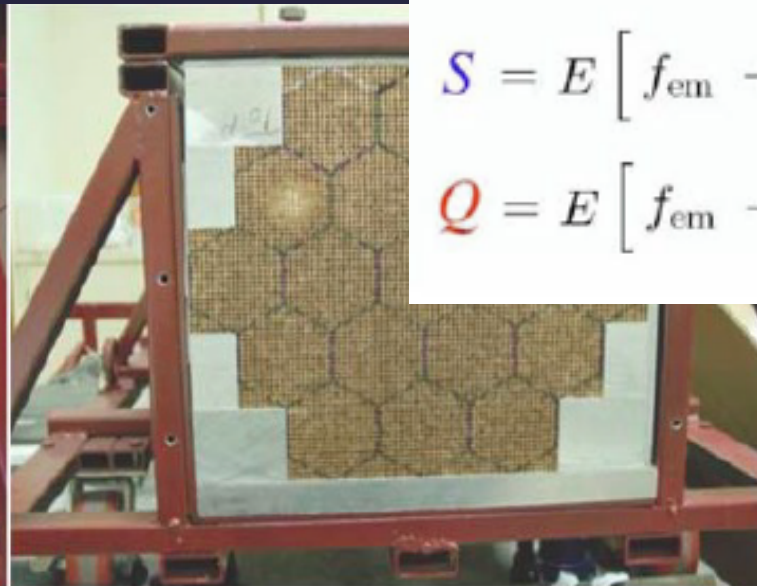

Market Price of Lu₂O₃

Assuming Lu₂O₃ at \$400/kg and 33% yield the cost is about \$18/cc.
Quotations received at \$22-25/cc.

DREAM

- Measure f_{EM} cell-by-cell by comparing Cherenkov and dE/dx signals
- Densely packed SPAgetti CALorimeter with interleaved Quartz (Cherenkov) and Scintillating Fibers
- Production of Cherenkov light only by em particles (f_{EM})
- Aim at: $\sigma_E/E \sim 15\%/\sqrt{E}$

$$S = E \left[f_{em} + \frac{1}{(e/h)_S} (1 - f_{em}) \right]$$

$$Q = E \left[f_{em} + \frac{1}{(e/h)_Q} (1 - f_{em}) \right]$$

PF calorimetry (CALICE)

- Design detectors for Pflow
 - ECAL and HCAL: inside solenoids
 - Low mass tracker
 - High granularity for imaging calorimetry
 - It also require sophisticated software

- Two proto-collaborations for ILC (ILD and SLD)
 - ECAL: Highly segmented S₁W or Scintillator-W sampling calorimeters
 - Transverse segmentation: $\sim 5 \times 5 \text{ mm}^2$
 - ~ 30 longitudinal sampling layers
 - HCAL: Highly segmented sampling calorimeters
Steel or W absorber+ active material (RPC, GEM)
 - Transverse segmentation: $1 \times 1 \text{ cm}^2 - 3 \times 3 \text{ cm}^2$
 - ~ 50 Longitudinal sampling layers !
 - Aiming at

$$\sigma_E / E < 3.5\%$$

Proposed CMS Si-based Endcap Calorimeter

- The CMS endcap calorimeters will be replaced for the high luminosity LHC running that aims to record an integrated luminosity of 3000 fb^{-1} .
- A dense and compact approach is proposed for both electromagnetic and hadronic calorimetry that uses a high lateral and longitudinal granularity.
- Recent advances in Si sensors in terms of cost per unit area and radiation tolerance, and advances in electronics and data transmission bring up the possibility of their use in such high granularity calorimetry.
- High granularity calorimeters are proposed for future ILC/CLIC detectors, for which they have been shown to provide very high resolving power for single particles in dense jet environments, with energies of several hundred GeV's.
- The challenges faced for high-luminosity LHC operation are mainly in the area of engineering (mechanical and thermal), data transmission and Level-1 trigger formation

EM fraction in hadronic calorimeters

Charge conversion of $\pi^{+/-}$ produces electromagnetic component of hadronic shower (π^0)

- e = response to the EM shower component
- h = response to the non-EM component

$$\pi = f_{em} e + (1 - f_{em}) h$$

Comparing pion and electron showers:

$$\frac{e}{\pi} = \frac{e}{f_{em} e + (1 - f_{em}) h} = \frac{e}{h} \cdot \frac{1}{1 + f_{em} (e/h - 1)}$$

Calorimeters can be:

- Overcompensating $e/h < 1$
- Undercompensating $e/h > 1$
- Compensating $e/h = 1$

The origin of the non-compensation problems

Compensation

- Non-linearity determined by e/h value of the calorimeter
- Measurement of non-linearity is one of the methods to determine e/h
- Assuming linearity for EM showers, $e(E_1)=e(E_2)$:

$$\frac{\pi(E_1)}{\pi(E_2)} = \frac{f_{em}(E_1) + [1 - f_{em}(E_1)] \cdot e/h}{f_{em}(E_2) + [1 - f_{em}(E_2)] \cdot e/h}$$

For $e/h=1 \rightarrow$

$$\frac{\pi(E_1)}{\pi(E_2)} = 1$$

- Response of calorimeters is usually higher for electromagnetic (e) than hadronic (h) energy deposits $\rightarrow e/h > 1$

Compensation

$$E_p = f_{em} e + (1 - f_{em}) h$$

$$h = f_{rel} \cdot rel + f_p \cdot p + f_n \cdot n + f_{inv} \cdot inv$$

Energy deposition mechanisms

- f_{rel} = Ionization by charged pions (relativistic shower component)
- f_p = spallation protons
- f_n = neutrons evaporation
- f_{inv} = invisible energy by recoil nuclei

Compensation:

- Tuning the neutron response using hydrogenous active material (L3 Uranium/gas calorimeter)
- Compensation adjusting the sampling frequency

Compensation by tuning neutron response

Hydrogen in active material (gas mixture)

Pb/Scintillator

Elastic n-p scattering:
efficient sampling of neutrons through
the detection of recoiling proton

Sampling fraction can be tuned to
achieve compensation

Material dependence

Z

Even though calorimeters are intended to measure GeV, TeV energy deposits, their performance is determined by what happens at the MeV - keV - eV level

IS

Summary

Radiation length:

$$X_0 = \frac{180A}{Z^2} \frac{\text{g}}{\text{cm}^2}$$

Critical energy:

[Attention: Definition of Rossi used]

$$E_c = \frac{550 \text{ MeV}}{Z}$$

Shower maximum:

$$t_{\text{max}} = \ln \frac{E}{E_c} - \begin{cases} 1.0 & e^- \text{ induced shower} \\ 0.5 & \gamma \text{ induced shower} \end{cases}$$

Longitudinal
energy containment:

$$L(95\%) = t_{\text{max}} + 0.08Z + 9.6 [X_0]$$

Transverse
Energy containment:

$$R(90\%) = R_M$$

$$R(95\%) = 2R_M$$

Problem:

Calculate how much Pb, Fe or Cu is needed to stop a 10 GeV electron.

Pb : $Z=82$, $A=207$, $\rho=11.34 \text{ g/cm}^3$

Fe : $Z=26$, $A=56$, $\rho=7.87 \text{ g/cm}^3$

Cu : $Z=29$, $A=63$, $\rho=8.92 \text{ g/cm}^3$

Longitudinal development of EM shower

- Shower decay: after the shower maximum the shower decays slowly through ionization and Compton scattering \rightarrow proportional to X_0

Resolution in Homogenous calorimeters

- Homogeneous calorimeters: signal = sum of all E deposited by charged particles with $E > E_{\text{threshold}}$
- If W is the mean energy required to produce a 'signal quantum' (eg an electron-ion pair in a noble liquid or a 'visible' photon in a crystal) the mean number of 'quanta' produced is $\langle n \rangle = E / W$
- The intrinsic energy resolution is given by the fluctuations on n.

$$\frac{\sigma_E}{E} = \frac{1}{\sqrt{n}} = \frac{1}{\sqrt{E/W}}$$

i.e. in a semiconductor crystals $W \approx 3$ eV (to produce e-hole pair)
1 MeV $\gamma = 350000$ electrons $\rightarrow 1/\sqrt{n} = 0.17\%$ stochastic term

- Fluctuations on n are reduced by correlation in the production of consecutive e-hole pairs: the Fano factor F

$$\frac{\sigma_E}{E} = \frac{1}{\sqrt{FE/W}}$$

The Fano factor depends on the material

Resolution in Sampling calorimeters

- Main contribution: sampling fluctuations, from variations in the number of charged particles crossing the active layers.
- Increases linearly with incident energy and with the finess of the sampling.
- Thus:

$n_{ch} \propto E / t$ where (t is the thickness of each absorber layer)

- For statistically independent sampling the sampling contribution to the stochastic term is:

$$\frac{\sigma_{smp}}{E} = \frac{1}{\sqrt{n_{ch}}} \propto \sqrt{\frac{t}{E}}$$

- Thus the resolution improves as t is decreased.
- For EM calorimeters the 100 samplings required to approach the resolution of homogeneous devices is not feasible
- **Typically**

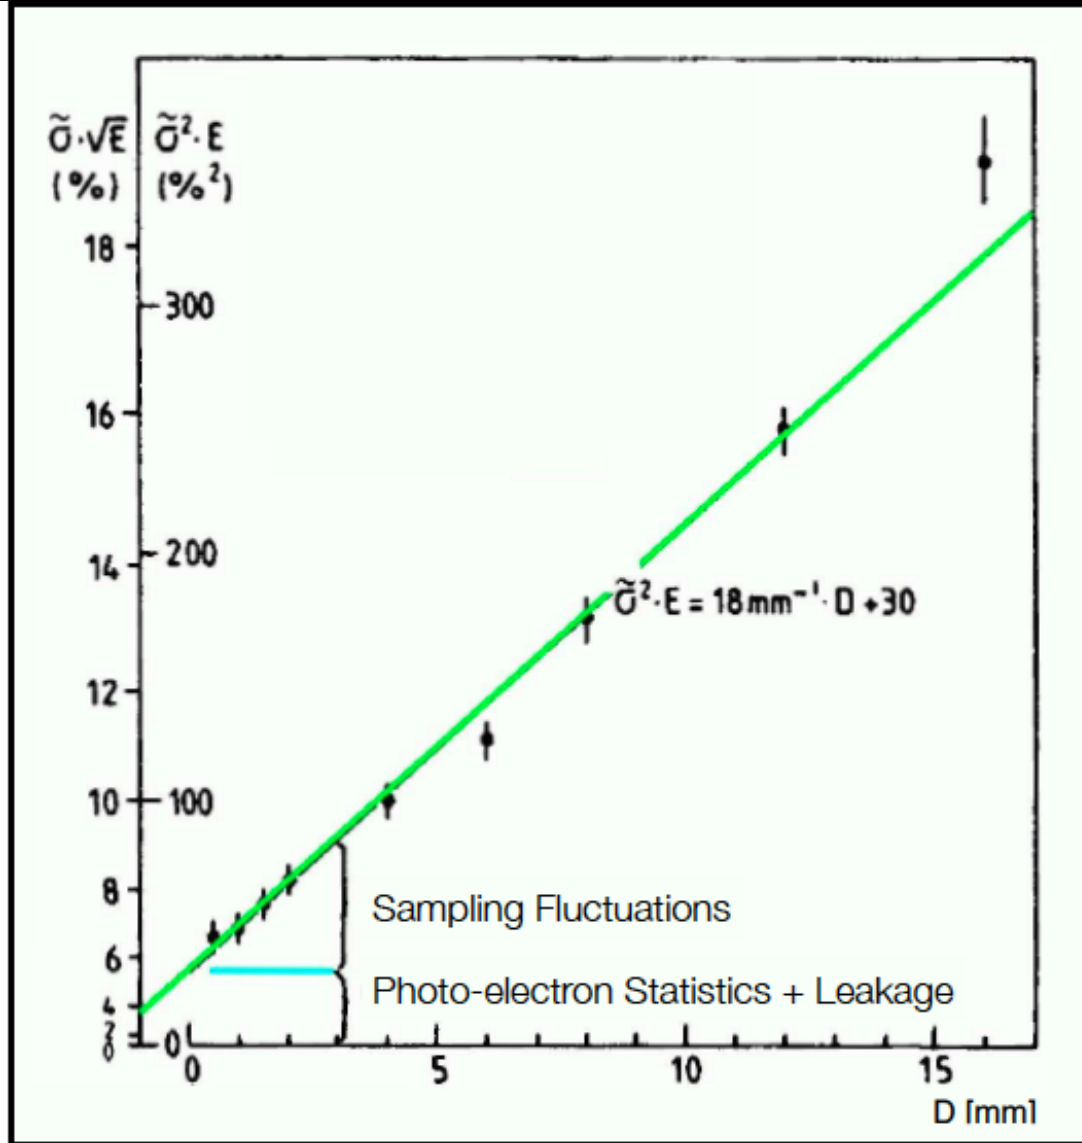

$$\frac{\sigma_{smp}}{E} = \frac{10\%}{\sqrt{E}}$$

Dependence on sampling

Measure energy resolution of a sampling calorimeter for different absorber thicknesses

Sampling contribution:

$$\frac{\sigma_E}{E} = 3.2\% \sqrt{\frac{E_c [\text{MeV}] \cdot t_{\text{abs}}}{F \cdot E [\text{GeV}]}}$$

Hadronic interactions

1st stage: the hard collision

- pions travel 25-50% longer than protons (~2/3 smaller in size)
- a pion loses ~100-300 MeV by ionization (Z dependent)

- Particle multiplication (string model)
 - average energy needed to produce a pion 0.7 (1.3) GeV in Cu (Pb)
 - Multiplicity scales with E and particle type
 - $\sim 1/3 \pi^0 \rightarrow \gamma\gamma$ produced in charge exchange processes: $\pi^+p \rightarrow \pi^0n$ and $\pi^-n \rightarrow \pi^0p$
 - Leading particle effect: depends on incident hadron type e.g fewer π^0 from protons, baryon number conservation

Nucleon is split in quark di-quark
 Strings are formed String hadronisation
 (adding qqbar pair)
 fragmentation of damaged nucleus

Hadronic interactions

2nd stage: spallation

- A fast hadron traversing the nucleus frees protons and neutrons in number proportional to their numerical presence in the nucleus.
- The nucleons involved in the cascade transfer energy to the nucleus which is left in an excited state
- Nuclear de-excitation
 - Evaporation of soft (~ 10 MeV) nucleons and α
 - fission for some materials
- The number of nucleons released depends on the binding E (7.9 MeV in Pb, 8.8 MeV in Fe)
- Mainly neutrons released by evaporation \rightarrow protons are trapped by the Coulomb barrier (12 MeV in Pb, only 5 MeV in Fe)

Dominating momentum component along incoming particle direction

isotropic process

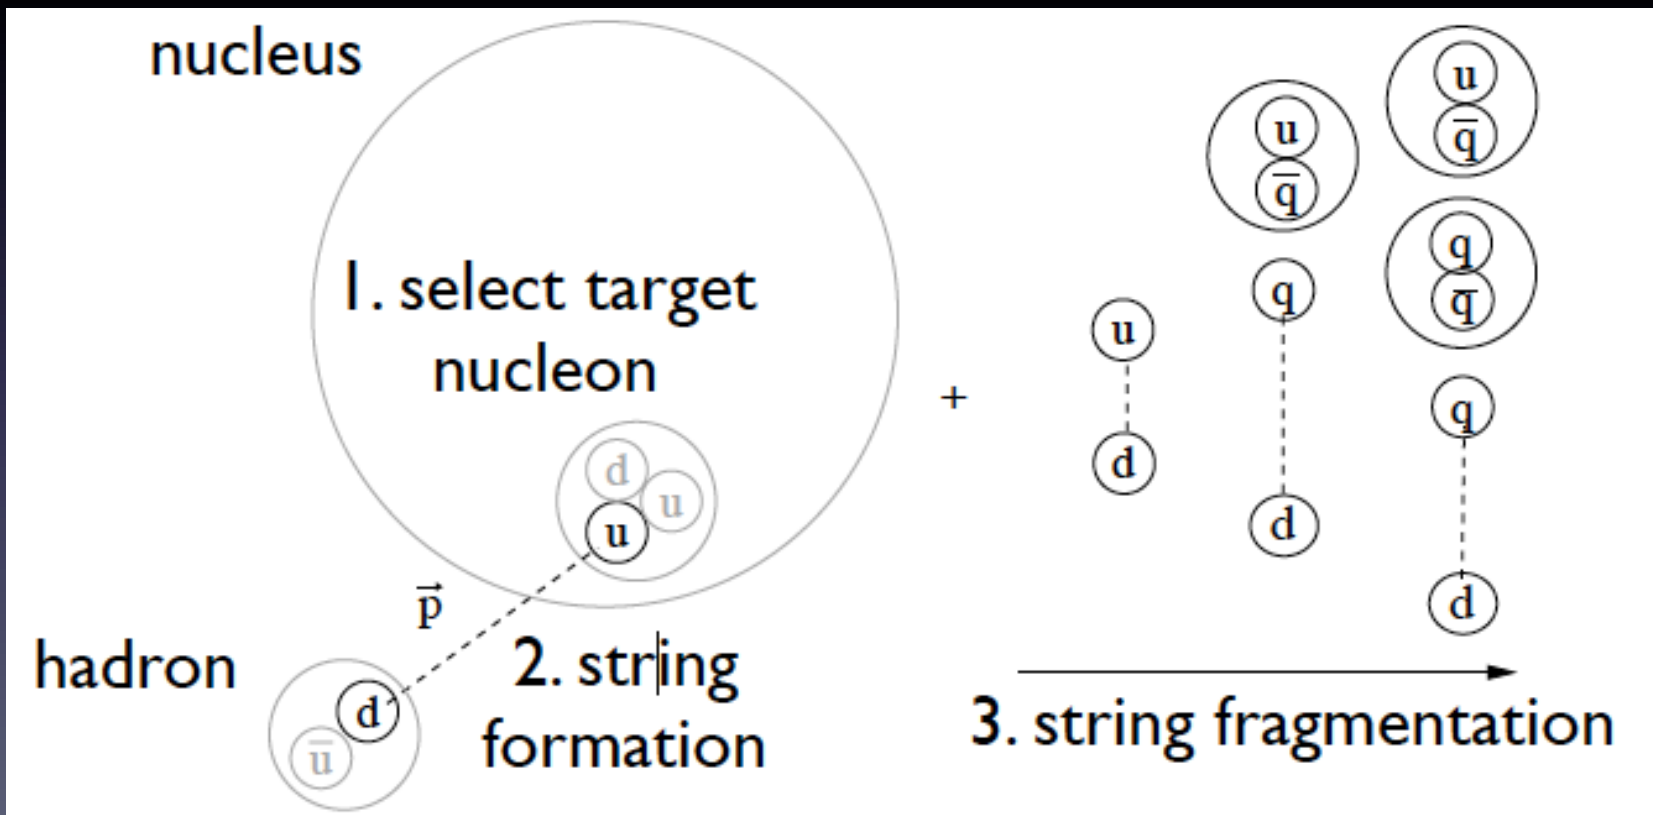

Hadronic shower

EM shower

Simulation

- Interaction of hadrons with $E > 10$ GeV described by string models
 - projectile interacts with single nucleon (p,n)
 - a string is formed between quarks from interacting nucleons
 - the string fragmentation generates hadrons

Simulation

- Interaction of hadrons with $10 \text{ MeV} < E < 10 \text{ GeV}$ via intra-nuclear cascades
- For $E < 10 \text{ MeV}$ only relevant are fission, photon emission, evaporation, ...

Approximations

- $\lambda_{\text{deBroglie}} \leq d \text{ nucleon}$
- nucleus = Fermi gas (all nucleons included)
- Pauli exclusion: allow only secondaries above Fermi energy
